REPUBLIC OF SENEGAL

Continuous Demographic and Health Survey in Senegal (Continuous DHS) 2012-2013

Final Report Year 1

Agence Nationale de la Statistique et de la Démographie (ANSD)
Dakar, Senegal

MEASURE DHS
ICF International
Calverton, Maryland, USA

July 2013

This report presents the findings of the first year of the Continuous Demographic and Health Survey in Senegal (Continuous DHS) 2012-2013, implemented from September 2012 through June 2013 by the *Agence Nationale de la Statistique et de la Démographie* (ANSD). The Continuous DHS 2012-2013 was funded by the Government of Senegal, USAID, UNICEF, and UNFPA. ICF International provided technical assistance for the survey through the USAID-funded MEASURE DHS program, whose objective is the collection, analysis, and dissemination of demographic and health data, particularly on fertility, mortality, family planning, maternal and child health, nutrition, and malaria.

Other agencies, such as the *Centre de Recherche pour le Développement Humain* (CRDH), and the *Laboratoire de Parasitologie of the Faculty of Medicin of the Université Cheikh Anta Diop* also participated in the implementation of the survey.

Additional information about the Continuous DHS 2012-2013 may be obtained from:

FOREWORD

The Continuous Demographic and Health Survey in Senegal (Continuous DHS 2012-2013), follows the DHS surveys of 1986, 1992, 1997, and 2005 and the EDS-MICS 2010-2011. Since publication of the 2011 survey, Senegal has embarked on a program of surveys in which phases of data collection are repeated at annual and other regular intervals. The Continuous DHS includes a section on the production of sociodemographic indicators (Household component) and another on assessing the availability of human and material resources as well as the quality of care provided by health services to the population (Health Facilities component). I am pleased with the quality of collaboration of the Ministry of Economy and Finance, which has joined the Ministry of Health and Social Action in this important endeavor.

The Continuous DHS 2012–2013 was carried out by the National Agency of Statistics and Demography (ANSD) with the technical assistance of ICF International. The Laboratory of Bacteriology of University Cheikh Anta DIOP (UCAD) supported implementation of the component on malaria parasitemia. I gratefully thank them.

This first phase of the Continuous DHS incorporates several themes from preceding DHS surveys, in particular, fertility, family planning, antenatal and postnatal care, prevention and management of childhood diseases, and childhood mortality. It also informs the issues related to child malnutrition through anthropometric measurements. Indicators having to do with the prevention of malaria and child nutrition are elaborated upon.

By implementing this survey, ANSD intends to provide users and producers of statistics, and policymakers, with a wide variety of updated and previously unpublished data, which is necessary for good economic and social planning.

Through this survey, ANSD continues its efforts to facilitate access to data for the scientific community. As with other DHS surveys, the database for the Continuous DHS can be downloaded online in order to promote further comprehensive studies. All documentation from the survey will be available online or directly from ANSD and ICF International. I am convinced that all users will benefit from this wealth of information, which will lead to better planning of their activities.

The implementation of this survey has mobilized substantial financial resources. The United States Agency for International Development (USAID), the United Nations Fund for Population Activities (UNFPA), the United Nations Children's Fund (UNICEF), and the government (ANSD) have provided funding. Technical and financial partners have also contributed technically to the implementation of this undertaking as members of the technical and steering committees of the project. I extend my sincere thanks.

My thanks also go to all institutional partners and others who contributed to the success of this important investigation. I express my deep gratitude to the people and to the departments of the government for their support and availability throughout the work of data collection.

The Ministry of Health and Social Action
Professor Awa Marie Coll SECK

ACKNOWLEDGMENTS

To ensure better monitoring of the achievement of the Millennium Development Goals (MDGs), Senegal has just completed in 2012-2013 the first phase of a Continuous Demographic and Health Survey. The survey is a part of the program of action of the Master Plan for Statistics, which covers the period 2012-2016, and which hopes to create a continuous flow of population data. This data will help meet the demand for more regular monitoring of the impact of global initiatives currently in progress that are aimed at strengthening health programs. This survey, part of the program of activities of the Master Plan for Statistics, answers the ongoing needs for data to plan, monitor, and evaluate population and health programs. The survey also helps to build capacity within the institutions of the host country for the collection, processing, analysis, and dissemination of data and results.

This regular exercise, which includes a household survey and a survey of health facilities, further illustrates the policy of rationalization of resources, both financial and technical, by the cooperative use and pooling of resources. It has involved the mobilization of significant financial resources as well as a number of resource persons. I would like, therefore, upon publication of this report to offer my sincere thanks to the government of Senegal and its development partners, including USAID, UNICEF, UNFPA, ICF International, and CRDH, who have supported ANSD throughout this operation.

Through this survey, ANSD reaffirms its commitments to new technologies by again using laptops for the collection and direct processing of data in the field. ANSD is, therefore, resolutely committed to the collection of survey data without paper questionnaires. This option consolidates its successful leadership and confirms the need to rely on and to have confidence in national expertise. I extend my congratulations to the experts at ANSD and my sincere thanks to ICF International and its subcontractor, the Center for Research in Human Development/Centre de Recherche pour le Développement Humain (CRDH, for their very valuable technical support.

I would also like to thank the technical and administrative staff of the Ministry of Health and Social Action, at both the central office and in outlying areas for their valuable assistance, the members of the Steering Committee and Technical Committee for their expertise and availability, and the staff from the Laboratory of Parasitology of the Cheikh Anta Diop University/Université Cheikh Anta Diop (UCAD) for their competence in the use of biological analyses.

I would like to express my deep gratitude and appreciation to the people in the localities surveyed as well as the local, traditional, religious, and administrative authorities for the warm welcome extended to the field staff.

Finally, I extend my congratulations to the field staff, drivers, interviewers, health technicians, team leaders and supervisors for their professionalism, dedication, and endurance, which have been crucial to the success of the survey.

I salute the collaboration of colleagues from all of the technical, administrative, logistical, and financial services of the National Agency of Statistics and Demography (ANSD) who came together to ensure a resounding success for this critical survey on 26 August 2013.

The General Director of ANSD

ADMINISTRATIVE MAP OF SENEGAL

OVERVIEW OF THE COUNTRY, OBJECTIVES, AND METHODOLOGY OF THE SURVEY

1

Fatou Bintou Niang CAMARA

This introductory chapter presents an overview of the country of Senegal. Context for subsequent chapters of the Continuous Demographic and Health Survey in Senegal 2012-2013 is accompanied by general information about survey objectives and methodology.

1.1 OVERVIEW OF THE COUNTRY

1.1.1 Geography

Senegal is a sub-Saharan coastal country situated on the far west of the African continent. It is bordered on the north by Mauritania, on the east by Mali, on the south by Guinea and Guinea Bissau, and on the west by the Atlantic Ocean. The Gambia, an enclave of land between the regions of Kaolack and Ziguinchor, crosses through Senegal along the lower section of the Gambia River.

Covering an area of 196,722 square kilometers, Senegal also borders the Atlantic Ocean with 700 kilometers of coastline. It is a flat country, with altitude rarely exceeding 100 meters. Its highest point, the summit of Mount Assiriki in southeastern Senegal, has a height of 381 meters.

Four rivers flow across the country from east to west: the Senegal, Gambia, Casamance, and Saloum rivers. This network is supplemented by some temporary seasonal streams as well as outflow from Guiers Lake in the north.

The reorganization of local and area-wide administrative divisions in Senegal was established by decree on September 10, 2008. The land area was redrawn to expand 11 administrative regions to 14, with the most recent additions being Kaffrine, Kédougou, and Sédiou, formed, respectively, from the former Kaolack, Tambacounda, and Kolda. The regions are further subdivided into 45 departments. There are 165 communes (assimilated into urban areas), 123 districts (arrondissements), and 383 rural communities.

1.1.2 Economy

In 2011, Senegal issued the Social and Economic Policy Document/(Document de Politique Economique et Social [DPES]). It was created as the established reference for action by government and development partners over the period 2011-15. The reports in this document highlight, among other issues, various economic problems that Senegal faces. Indicators for the period 2005-11 show relative stagnation with regard to poverty, explained in part by a growth rate, on average, of 0.5 percent GDP per capita per year. Although the incidence of new poverty declined slightly, it was accompanied by an increase in the overall number of poor during the period. Poverty is higher in rural areas than in urban centers. These results highlight both the fragility of the Senegalese economy and its ability, over the long term, to improve the living conditions of the population in a sustainable manner. In addition in 2011, the outstanding public debt, both domestic and foreign, increased markedly over the four years before the survey, despite the cancellation of debt registered under the HIPC (highly indebted poor countries) initiatives. The total outstanding foreign debt reached 39.7 percent of GDP, compared with 26.0 percent in 2008. This situation must be reversed quickly in order to include Senegal in the reduction of poverty and acceleration of achievement of the Millennium Development Goals (MDG) by 2015.

1.1.3 Population

Senegal has amassed economic and sociodemographic data from numerous surveys conducted over the last 30 years. Indeed, in addition to three censuses (Recensement Général de la Population [General Census of the Population (RGP)] in 1976, Recensement Général de la Population et de l'Habitat [General Census of the Population and Housing (RGPH)] in 1988, and RGPH in 2002), several national surveys have been conducted, including the Senegalese Survey on Fertility in 1978, the Survey on Migration and Urbanization in Senegal in 1993, the Senegalese Household Survey (1994/1995 and 2001/2002), five Demographic and Health Surveys (1986, 1992/1993, 1997, 2005 and 2010-2011), the National Survey on Child Labor in Senegal in 2005, and the Survey Monitoring Poverty in Senegal in both 2006 and 2011. These investigations have yielded basic demographic indicators at different times that contribute to the monitoring and evaluation of projects and development programs.

The population of the country has nearly doubled between 1988 (RGPH) and 2012, increasing from 6,896,000 to 13,207,873 inhabitants (with 6,527,659 men and 6,680,214 women). The mean population density is 68 inhabitants per square kilometer. However, this population is unevenly distributed among the 14 administrative regions of the country. The highest population totals are found in the regions of Dakar, Thiès, and Diourbel with, respectively, 2,702,203 inhabitants (20.5 percent of the total population), 1,743,707 inhabitants (13.2 percent), and 1,442,418 inhabitants (10.9 percent), while the northern and eastern regions of the country continue to be characterized by low population. The Kédougou region has the fewest residents, with 137,485 inhabitants (1.0 percent). The largest region, Tambacounda, has only about 6 percent of the population.

The high rate of population growth observed between 2002 and 2012 (2.69 percent) is mainly due to sustained high fertility (a TFR of 5.0 in 2010-2011) and declining infant mortality (from 61 percent in 2005 to 47 percent in 2010-2011). Rapid population growth has resulted in an extremely young population, with more than 50 percent of the country's inhabitants under age 20.

The illiteracy rate is 65 percent at the national level. This illiteracy rate varies from one region to another: the lowest rate was observed in Dakar (35 percent); Ziguinchor follows with 43 percent. In other areas, except for Saint-Louis and Thiès, illiteracy exceeds 75 percent.

Although Senegal has more than 20 ethnic groups, more than 90 percent of the population belongs to five dominant ethnic groups: Wolof (43 percent), Pular (24 percent), Séér (15 percent), Diola (5 percent), and Mandingue (4 percent).

Senegal's population is predominantly Muslim (94 percent), with the remainder being Christian (4 percent), as well as animist and other religions (2 percent).

1.1.4 Health Policy and Health Situation

Policy in the health sector remains on track to achieve the objectives of the Millennium Development Goals (MDGs) and the priority goals of the second National Health Development Plan (NHDPII, 2009-2011) (Plan National de Développement Sanitaire [PNDS]). Specific goals are to reduce maternal and infant/child mortality, achieve fertility control, and increase access for the poor to basic services.

The share of the state budget allocated to the health sector has increased steadily in recent years, resulting in a steady rise in the budget of the Ministry of Health. The budget grew from 36 billion CFA francs in 1998 to 90.5 billion in 2008, 105.9 billion in 2011, and 110.5 billion in 2012. This budget now represents 10.4 percent of the operating budget of the State.

In 2012, Senegal had 80 hospitals (including 28 public and 52 private), 131 health centers (81 public and 50 private) and 1,367 health posts (1,108 public and 259 private). In addition, there were 1,506 health huts. However, in terms of health infrastructure coverage, Senegal has not yet achieved the standards¹ recommended by the World Health Organization (WHO).

The last two decades have been marked by improved health status as evidenced by the trend in most indicators monitored by health programs. Infant and child mortality rates, while still high, have declined significantly. Indeed, the rate of child mortality fell from 121 per 1,000 live births in 2005 to 72 per 1,000 live births in 2010-2011, and infant mortality dropped from 61 per 1,000 live births in 2005 to 47 per 1,000 live births in 2010-2011. The maternal mortality ratio stood at 392 per 100,000 live births in 2010-2011.

The NHD/PNDS attaches great importance to the following areas: epidemiological surveillance, reproductive health, STDs/AIDS, and control of endemic diseases such as malaria. The latter endemic, one of the principal causes of morbidity, is in retreat, mainly because of the proactive stance of the National Program against Malaria (Programme National de Lutte contre le Paludisme [NPAM/PNLP]).

The relatively low level of HIV prevalence in the general population age 15 to 49 (0.7 percent in 2010-2011) remains stable.

In 2010-2011, more than 9 of 10 mothers (93 percent) were seen by trained medical personnel during pregnancy. For births in the five years before the 2010-2011 survey, 65 percent of mothers benefited from the assistance of trained medical staff at delivery. Immunization coverage among children under age 5 has improved (63 percent in 2010-2011).

1.2 INSTITUTIONAL FRAMEWORK, OBJECTIVES, AND METHODOLOGY OF THE SURVEY

1.2.1 Institutional Framework

The government of Senegal completed in 2012-2013 the first phase of a continuous demographic and health survey (DHS) in accordance with the action program of the Statistics Master Plan. The survey will cover the period 2012-2017 and will provide a continuous flow of data on the population. This data will help meet the demand for more regular monitoring of coverage and impact indicators resulting from current global initiatives aimed at strengthening health programs. The Continuous DHS was conducted by the National Agency of Statistics and Demography (ANSD) with technical assistance from ICF International, the U.S. organization in charge of the international Demographic and Health Surveys program. ICF International is a subcontractor to the Center for Research in Human Development (Centre de Recherche pour le Développement Humain [CRDH]). The Cheikh Anta Diop University (Université Cheikh Anta Diop [UCAD]) parasitology laboratory provided technical support for the testing component for malaria (staff training, sampling, analysis of blood samples, and data analysis).

A steering committee, established to implement the survey, included the Ministry of Health and development partners in addition to the DHS technical team. The government of Senegal has received financial support from the U.S. Agency for International Development (USAID), United Population Fund (UNFPA), and United Nations Children's Fund (UNICEF).

¹ WHO norms: one health post for every 10,000 inhabitants, one health center for every 50,000 inhabitants, and one hospital for every 150,000 inhabitants.

1.2.2 Objectives

The Continuous DHS has two main objectives: (1) to meet ongoing needs for data to plan, monitor, and evaluate health programs and populations and (2) to build capacity within institutions to collect, process, analyze, disseminate, and use data. The survey has other potential benefits. Maintenance of a central office and field staff over time leads to a de facto institutionalization of the DHS process, which brings benefits that a single DHS performed every five years cannot. Data quality should improve, and the need for technical assistance should diminish. The design of the Continuous DHS also allows for greater flexibility to meet the statistical requirements of the country, so each phase of the survey can be adapted to specific topics for study, which is difficult to do in a five-year DHS.

These objectives are consistent with the fundamental principles of the Global Health Initiative (GHI), recently launched by the government of the United States to support results that improve health, especially among women and young children, by enhancing health system performance in developing countries. The GHI is a program based on results. Counted among its fundamental principles are commitment to decision making based on knowledge and improved monitoring and evaluation. The commitment to respecting national ownership is an integral part of the GHI. Accordingly, the task of carrying out the Continuous DHS belongs to Senegal. Senegal is the first country in Africa and the second country in the world (after Peru) to undertake a continuous survey in the DHS program.

1.2.3 Methodology

Questionnaires

To allow for flexibility in the design of each phase of the Continuous DHS, the standard questionnaire has been shortened. Changes deemed necessary have been made to the basic questionnaires to accommodate the sociocultural, country-specific requirements of Senegal and to meet the needs of users. In addition, to ensure the comparability of results at the international level, these changes were kept to a minimum. The new questionnaire includes a complete birth history to allow calculation of rates of fertility and mortality and provides most of the recommended indicators, including those of UNICEF.

In addition, Senegal, which had included HIV testing in the Enquête Démographique et de Santé et à Indicateurs Multiple (EDS-MICS) 2010-2011, decided to repeat the testing during the 2016 -2017 phase of the Continuous DHS.

Two questionnaires were used: a Household Questionnaire and a Woman's Questionnaire for women age 15-49. The specific content of these questionnaires follows.

The Household Questionnaire was used to list all the usual members and visitors in the selected households. The cover page contained information on how to identify the household, use the results of the interview to calculate the coverage rates for the survey, and monitor the field and office. This questionnaire collected information on the usual household members and visitors who spent the night preceding the interview. Information included gender, age, education (school age and pre-school), survival of parents, reporting of the civil status of children, care of preschool-age children, and child labor.

Further information was collected concerning household characteristics (source of water, type of toilet, building material, availability of electricity, ownership of durable goods, etc.); ownership, use, and insecticide treatment of mosquito nets; and use of iodized salt² in food preparation. Questions regarding access to land ownership and residential security were also asked. This information was collected to assess the environmental and socioeconomic living conditions of the people interviewed.

Moreover, one of the key objectives of the Household Questionnaire was to identify women eligible for individual interviews and children eligible for anthropometry, testing for anemia, and testing for malaria parasitemia. Anthropometric measurements were collected for all children under age 5 to determine their nutritional status (wasted, underweight, or stunted). In the households sampled, testing for anemia and malaria parasitemia was performed on children age 6-59 months.

After obtaining informed consent from parents or caretakers of children, a blood sample was taken from children age 6-59 months. A test measuring the level of hemoglobin and the rapid diagnostic test (RDT) for malaria were undertaken in the field. In addition, a thick drop of blood was collected on a slide and was later analyzed in the laboratory to estimate the prevalence of malaria.

The Woman's Questionnaire is the central element of the survey. It includes a cover page similar to the one for the Household Questionnaire. On it is recorded information for household identification, results of the interview used to calculate the coverage rate for the survey, and data for monitoring field and office. In addition, this questionnaire consists of 10 sections that collect information on the following topics:

- *Sociodemographic characteristics:* place of residence, age and date of birth, schooling, literacy, nationality, religion, ethnicity, and media exposure
- *Reproduction:* live births that a woman has had during her life as well as their survival status at the time of the survey, the state of pregnancy at the time of the survey, and knowledge of the fertile period in the menstrual cycle
- *Knowledge and use of contraception:* knowledge of and past and current use of various contraceptive methods, as well as sources of supply. Includes place and date of female sterilization, as well as the reasons for non-use of a method
- *Pregnancy, breastfeeding, immunization, and child health:* births in the five years preceding the survey. The first part provides information on the period of pregnancy; antenatal care, including tetanus toxoid; place of delivery and qualifications of the person who assisted the woman; postnatal care; and return of menstrual periods and resumption of sexual intercourse after childbirth. Questions on breastfeeding concern its frequency and duration, the type of feeding (breast or formula), as well as the use of various nutritional supplements. The second part focuses on vaccinations included in the Expanded Program on Immunization (EPI) and the health of children under age 5, particularly the prevalence and treatment of fever, cough, and diarrhea
- *Marriage and sexual activity:* marital status of women, cohabitation with spouse, type of marriage (monogamy or polygamy), age at first marriage, age at first intercourse, as well as sexual activity

² In all households surveyed, salt used for cooking is tested to determine its iodine content. Results of the test indicate the proportion of women and children living in households using sufficiently iodized salt.

- *Fertility preferences*: desire for additional children, preferred interval between births, and opinion on family size
- *Female genital mutilation*: practices among girls under the age of 15 years

Manuals and other technical documents

In addition to the questionnaires, other documents were developed by the technical team. These include the following:

- Interviewer's manual
- Team leader's manual
- Mapping and household listing manual
- Manual for tablet PC use (computer-assisted interview (CAPI)
- Anthropometric manual
- Malaria testing manual
- Anemia testing manual
- Assignment sheets for interviewers/supervisors
- Forms for supervision and management of testing (anemia and malaria)
- Reference sheets for testing (anemia and malaria)

ANSD ensured the reproduction of a sufficient number of these various documents.

Testing for hemoglobin and malaria parasitemia

In the households selected, children age 6-59 months were eligible for anemia and parasitemia testing. Protocols for anemia and malaria parasitemia tests were approved by the Ethics Committee (Internal Review Board) of ICF International in Calverton, Maryland, USA, and by the National Ethics Committee for Health Research (CNERS) of Senegal.

To obtain blood samples from eligible persons, each field team included an interviewer-health technician assigned to blood sampling. In addition to the interviewer training, this technician received special training on all aspects of the protocols for anemia testing. Prior to taking the sample for each eligible child, the technician requested informed consent from the person responsible for the child after explaining the sampling procedures, confidentiality of the test, and conditions for referral support as needed.

Hemoglobin test. The hemoglobin test is the primary method for diagnosing anemia; it is carried out using the HemoCue system. Before collecting blood, the finger was cleaned with an alcohol swab and dried in the air. Then the finger (or heel of children under age 1 who were very thin) was pricked with a non-reusable, sterile retractable lancet. A drop of blood was collected in a microcuvette and then put into a HemoCue photometer, which indicated the hemoglobin level. These results were recorded in the Household Questionnaire and communicated to the person tested or to the parent/responsible adult, explaining the significance of the results. If the person had severe anemia (hemoglobin level <7 g/dl), the interviewer provided her or him with a referral sheet to seek care from a health service.

Test for malaria parasitemia. Malaria parasitemia testing was carried out on children age 6-59 months. Two tests for the diagnosis of malaria were carried out: a rapid diagnostic test (RDT), with results communicated to the parents/person in charge of the child, and examination of a thick blood smear. Children testing positive on the RDT were referred to a health service by the laboratory technicians for the survey, according to the protocol in effect.

In addition, after a blood sample was drawn, thick blood smears were put on a glass slide and analyzed in the laboratory of the Department of Parasitology, Faculty of Medicine, Cheikh Anta Diop University/Université Cheikh Anta Diop, UCAD), Dakar.

Sampling

The Continuous DHS 2012-2013 is directed at two target groups: women age 15-49 and children age 0-59 months. The scope of the survey covers the entire country and is taken from a stratified national sample of approximately 4,400 households and drawn in two stages. This sample can produce, for most indicators, representative results from the four major regions:³

- West, includes Dakar and Thiès
- Center, encompasses Diourbel, Fatick, Kaolack, and Kaffrine
- North, contains Matam, Louga, and Saint-Louis
- South, comprises Tambacounda, Kolda, Kédougou, Sédiou, and Ziguinchor

To constitute the sample, 200 census districts (CDs) (79 urban and 121 rural) were drawn for the first sampling stage by a systematic drawing with probability proportional to size (number of households in the CD). An enumeration of households in each CD provided a list of households from which a sample of 22 households was drawn for the second stage through a systematic drawing with equal probability. Within this sample of households, 8,500 women age 15-49 and 8,200 children were expected to be found eligible for the survey. All women age 15 to 49 years, ordinarily residing or visiting the home, were identified in these households and were individually interviewed. All children age 6-59 months were eligible to take the screening tests for malaria and anemia.

During the Continuous DHS, a total of 4,399 households were selected, and 4,232 occupied households were identified at the time of the survey. Among these 4,232 households, 4,175 were able to be successfully interviewed, for a response rate of 99 percent (Table 1.1). The response rate is practically the same in both rural areas (98.8 percent) and urban areas (98.4 percent).

In the 4,175 households surveyed, 9,042 women age 15-49 were identified as eligible for the individual interview, and the interview was conducted successfully with 8,636 of them, for a response rate of 95.5 percent. The response rates were almost the same for both urban and rural areas.

Table 1.1 Results of the household and individual interviews

Number of households, number of interviews, and response rates, according to residence, Continuous DHS, Senegal 2012-13

Result	Residence		
	Urban	Rural	Total
Household interviews			
Households selected	1,737	2,662	4,399
Households occupied	1,665	2,567	4,232
Households interviewed	1,638	2,537	4,175
Household response rate ¹	98.4	98.8	98.7
Interviews with women age 15-49			
Number of eligible women	3,504	5,538	9,042
Number of eligible women interviewed	3,360	5,276	8,636
Eligible women response rate ²	95.9	95.3	95.5

¹ Households interviewed/households occupied.

² Respondents interviewed/eligible respondents.

1.2.4 Realization of the Continuous DHS

The Continuous DHS was conducted in three main stages: 1) the preparatory phase, 2) the mapping and enumeration of households in selected clusters, and 3) the actual data collection. For each of these last two stages, training was given to persons recruited for field activity needs.

³ Thus, the term *region* or *area* used in the text refers to one of these four major regions.

Preparatory phase. The preparatory phase started in 2011 with the development of the first project document and ended in 2012 just before the training for survey staff members. Project and advocacy documents and support for data collection were developed during this phase.

A technical team assigned to manage the project, assisted by ICF International, was set up at ANSD. The laboratory assigned to parasitology was also designated. It was responsible for laboratory analyses and the training and supervision of health technicians.

Mapping and enumeration. Training for cartographers was conducted in June 2012, and field work took place from July to August 2012. The training included theoretical lectures on the definition of basic concepts, procedures and cartographic methodology, as well as field practice and ongoing assessments. Based on various assessments undertaken during training, 19 staff cartographers (divided into 4 teams, each consisting of a team leader and 4 to 5 cartographers) were selected to implement the mapping and enumeration of households in the selected CDs.

Both the authorities and populace were made aware of the survey through letters and circulars to regional authorities and meetings with local officials. During mapping, this activity was part of the scope of work for these teams. Information and awareness sessions were organized before the start of data collection.

Recruitment and training of field staff. Because this is a continuous survey, a limited number of the same field workers from the EDS-MICS 2010-11 were renewed. These field workers were selected on the basis of their maturity, ability to communicate, level of education, knowledge of the national languages, practical computer experience, and their availability to work on a permanent basis with the survey. Every effort was made to hire trained field staff whose profile was predefined by the technical survey team.

Field workers were in training (beginning on August 13, 2012) for about three weeks, covering all aspects of the investigation. Presentations on specific topics were given by resource persons from the Ministry of Health and Social Welfare or other appropriate institutions.

Training on the use of tablet PCs, the main collection tool, was provided by experts from ANSD, ICF International, and CRDH. All field staff were trained on all modules except for the one on biological testing, which was reserved only for the health technicians. At the end of training, staff members received additional training in technical monitoring, organization, and field logistics, as well as contact with authorities and the populace.

Training in biological testing (anemia and malaria parasitemia) and anthropometric measurements was performed by the staff of the parasitology laboratory and a nutritionist. Health technicians practiced testing in the field, and all field staff practiced anthropometric measurements at health centers in Dakar.

Data collection. After the training, three teams were formed for the fieldwork; each team consisted of three female interviewers in charge of interviewing both the households and the women using tablet PCs; a health technician to perform anthropometric measurements, as well as malaria and anemia testing using a paper questionnaire; and a team leader who, from time to time, would administer the household questionnaire using tablet PCs. This team leader was responsible for the performance and management of his or her team. The team leader also served as an assistant to the health technician for taking anthropometric measurements.

Data collection in the field lasted eight months (from September 15, 2012, to June 15, 2013) and was done in two rounds of four months each, with the first session from September to January and the second from February to June, which entailed visits to 200 CDs.

Statisticians were recruited to provide supervision of the data collection activities. Therefore, frequent supervisory visits were organized to ensure the quality of data collected in the field. Meanwhile, a supervisory visit organized by the National Ethics Committee for Health Research (CNERS) helped ensure compliance with ethical regulations in the field.

Running of data quality tables. Quality control was ensured by supervision and monitoring of the teams during fieldwork activities. Each team leader was responsible for the quality of the team's work: he or she held regular meetings with the team to strengthen training and correct errors committed during data collection. In addition, the team leaders had to re-interview about 5 percent of the households to monitor data quality. These re-interviews, limited to certain sections of the questionnaire, were carried out before leaving the CD. Team leaders used these re-interviews to closely monitor the reasons for "non-responses," particularly absences from the household and refusals.

Finally, a set of control tables was produced by the computer programmer at least once every two weeks throughout the data collection to check the validity of the tables that had been entered. Once produced, these tables were examined by the technical team of the survey, and eventual problems detected in these tables were reviewed with the three field teams to improve response rates and data collection quality.

Data processing. Data collection was carried out with tablet PCs. After checking the data in the field, the data files were transferred by CD to the ANSD central office in Dakar. These data files were then recorded, compiled, and processed on a central computer. Data from each CD were checked and a single file of cleaned data was created after the files from all the CDs were recorded and approved. Recording, monitoring, and compilation of data were carried out by two computer scientists recruited for the Continuous DHS. After merging the files, the final errors detected were processed with technical support from the computer science expert from ICF International.

Laboratory analysis of blood samples. The test for malaria parasitemia was performed by the parasitology laboratory of UCAD. Processing of the samples of thick blood smears was done during data collection in the field.

CHARACTERISTICS OF HOUSEHOLDS AND WOMEN

2

Papa Mabèye DIOP

Key Findings

- More than half of the households in Senegal have electricity (57 percent percent), with wide disparity in usage between urban (88 percent percent) and rural (28 percent) areas.
- Approximately 69 percent of households have access to tap water or a public standpipe that provides water. Nearly two out of five households have improved toilets that are not shared (39 percent percent); however, many households (38 percent percent), mainly rural, do not have any type of toilet.
- About two-thirds (64 percent percent) of women age 15-49 are married/in union, and more than half (55 percent percent) have no education.

The objective of this chapter is to describe the background characteristics and living conditions of women and children who took part in the Continuous DHS 2012-2013. The first part deals with housing characteristics, such as the type of drinking water supply, toilet, and flooring material, and the availability of electricity. The second part of the chapter describes characteristics of women, such as their age, marital status, religion, ethnicity, place of residence (urban or rural and major regional area), and level of education.

2.1 LIVING CONDITIONS

2.1.1 Source of Drinking Water

Table 2.1 presents the distribution of households and population by source of drinking water. Most Senegalese households are supplied with drinking water from an improved source, regardless of residence, (76 percent overall, 90 percent of urban households and 63 percent of rural households). Tap water is the most common source, with 69 percent of all households (86 percent urban and 52 percent rural). Other improved sources (protected wells, bottled water, and rainwater) represent only 7 percent of all households (4 percent for urban areas and 10 percent in rural areas). The distribution of the population by source of drinking water differs little from that of households.

Table 2.1 also shows that for nearly 9 Senegalese households in 10 (89 percent), it takes less than 30 minutes to get water; 52 percent have piped tap water at home. This proportion is lower in rural than in urban areas (82 percent versus 96 percent).

Most of the time, water is not subject to any treatment before use, especially in urban areas (71 percent of all households, 81 percent in urban areas and 62 percent in rural areas). In 13 percent of cases, households treat water with bleach or chlorine, or, in 18 percent of cases, they strain it through a cloth. This method of treating water is mostly used in rural areas (29 percent compared to 7 percent in urban areas). Boiling, solar disinfection, and other filtering methods (ceramic, sand, etc.) are rarely used.

Table 2.1 Household drinking water

Percent distribution of households and de jure population by source of drinking water, time to obtain drinking water, and treatment of drinking water, according to residence, Continuous DHS, Senegal 2012-2013

Characteristics	Households			Population		
	Urban	Rural	Total	Urban	Rural	Total

Number	2,042	2,133	4,175	15,378	22,139	37,518

¹ Respondents may report multiple treatment methods, so the sum of treatments may exceed 100 percent.

² Appropriate water treatment methods include boiling, bleaching, straining, filtering, and solar disinfecting.

2.1.2 Type of Toilet Facilities

Access to adequate sanitation facilities and use of good hygiene practices are important objectives for the achievement of the Millennium Development Goals (MDGs). The results of the Continuous DHS 2012-2013, presented in Table 2.2, show that 39 percent of Senegalese households use some type of improved toilet facility that is not shared. As expected, use of improved toilets is more common in urban than rural areas (41 percent compared to 30 percent). In addition, one in four households (25 percent) has access to improved, shared toilet facilities. There are also significant differences according to place of residence (41 percent in urban versus 9 percent in rural areas). Moreover, 15 percent of households have access only to traditional latrines, and 20 percent do not have access to any toilet at all. In rural areas, the corresponding figures are 23 percent and 38 percent compared with, respectively, only 7 percent and 2 percent in urban areas. In the 2010-2011 (EDS-MICS), the proportion of households with no toilet was 18 percent overall, and 33 percent in rural areas versus 2 percent in urban areas.

Table 2.2 Household sanitation facilities

Percent distribution of households and de jure population by type of toilet/latrine facilities, according to residence, Continuous DHS, Senegal 2012-2013

Type of toilet/latrine facility	Households			Population		
	Urban	Rural	Total	Urban	Rural	Total
Improved, not shared facility						
Flush/pour flush to piped sewer system	12.3	0.0	6.0	10.1	0.0	4.2
Flush/pour flush to septic tank	16.4	6.2	11.2	21.0	7.0	12.7
Ventilated improved pit (VIP) latrine	4.3	4.8	4.6	6.8	5.5	6.1

Total	100.0	100.0	100.0	100.0	100.0	100.0
Number	2,042	2,133	4,175	15,378	22,139	37,518

¹ Facilities that would be considered improved if they were not shared by two or more households.

2.1.3 Housing Characteristics

Table 2.3 shows that overall, 57 percent of surveyed households have electricity. The results indicate significant disparities depending on residence. Rural areas are considerably less well off, with only 28 percent of households having electricity, compared with 88 percent in urban areas (Figure 2.1). In addition, it should be noted that between 2010 and 2013, the level of household access to electricity in rural areas has changed little (27 percent in the EDS-MICS 2010-2011 and 28 percent in the Continuous DHS 2012-2013).

Certain types of flooring may facilitate the spread of germs that cause disease. For this reason, questions were asked about the type of material used for flooring in rooms utilized for residential housing. In Senegal, 74 percent of households have a home where the floor is cement, ceramic tile, or vinyl (compared with 64 percent in the EDS-MICS 2010-2011) while 25 percent of households have flooring made of earth, sand, or dung (versus 34 percent in the EDS-MICS 2010-2011). Whatever the area of residence, cement remains the main flooring material used in rooms for residential living. Rural households with flooring made from earth/sand or dung still remain high (45 percent). In urban areas, 46 percent of households live in housing where the floor is made of cement, while in 32 percent the floor is covered in ceramic tiles.

Table 2.3 also shows the distribution of households according to the number of rooms used for sleeping. In 61 percent of cases, households use three rooms or more for sleeping and in 17 percent two rooms. It is also notable that cooking is done inside the house in 68 percent of households, while the kitchen is in a separate building in 21 percent of cases, and cooking is done outside in 6 percent of households.

Table 2.3 Household characteristics

Percent distribution of households by housing characteristics and percentage using solid fuel for cooking, both according to residence, Continuous DHS, 2012-2013

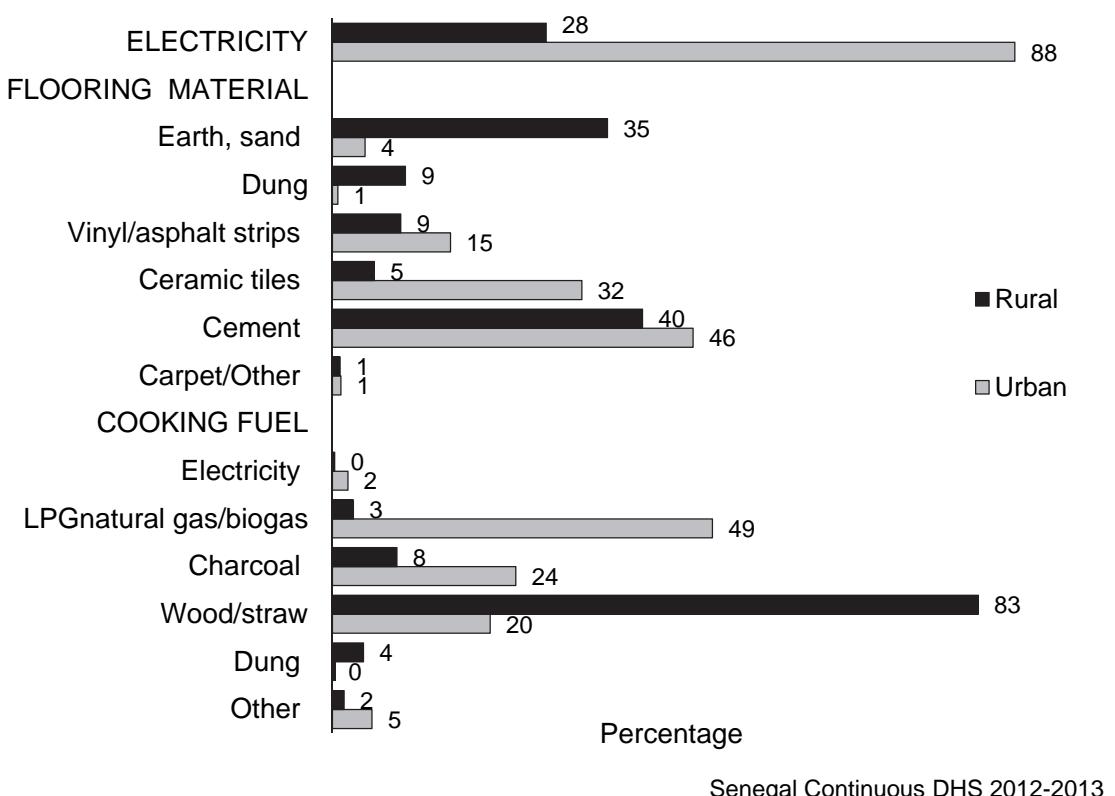

Household characteristic	Residence		
	Urban	Rural	Total
Electricity			
Yes	87.8	27.5	57.0

Carpet	1.1	0.3	0.7
Other	0.0	0.5	0.2
Total	100.0	100.0	100.0
Rooms used for sleeping			
One	36.0	8.5	21.9
Two	16.6	17.6	17.1
Three or more	47.3	74.0	60.9
Missing	0.1	0.0	0.0
Total	100.0	100.0	100.0
Place for cooking			
In the house	71.4	64.9	68.1
In a separate building	16.0	25.2	20.7
Outdoors	6.2	5.7	5.9
Other	6.4	4.3	5.3
Total	100.0	100.0	100.0
Cooking fuel			
Electricity	2.0	0.3	1.2
LPG/natural gas/biogas	48.9	2.7	25.3
Wood	23.6	8.3	15.8
Straw/shrubs/grass	20.3	83.1	52.4
Animal dung	0.0	4.0	2.1
Other	5.1	1.5	3.3
Total	100.0	100.0	100.0
Percentage using solid fuel for cooking ¹	44.0	95.5	70.3
Number	2,042	2,133	4,175

LPG = Liquefied petroleum gas

¹Includes coal/lignite, charcoal, wood, straw/shrubs/grass, agricultural crops, and animal dung

To assess the level of pollution inside the home, the survey asked about the type of fuel used for cooking in the household. Overall, more than half of households (52 percent) use straw/shrubs/grass. This proportion varies significantly by area of residence: 83 percent in rural areas and 20 percent in urban areas. Urban households more frequently use gas for cooking (49 percent compared with 3 percent). Overall, a majority of households (70 percent) use solid fuels for cooking.

Figure 2.1 Household characteristics by area of residence

2.1.4 Quintiles of Household Wealth

Table 2.4 shows the distribution of the de jure population by wealth, according to residence and region. The index of wealth is constructed from data on household goods and housing characteristics (electricity, type of water supply, type of toilet, flooring material, etc.) collected in the Household Questionnaire. Each of these goods and characteristics is assigned a weight (score or coefficient) generated from a principal component analysis. The resulting scores of goods are standardized according to a standard normal distribution with a mean of 0 and a standard deviation of 1 (Gwatkin et al, 2000). Then each household is assigned a score for each item and, summing all scores per household, individuals are ranked according to the total score of the household where they reside. The sample is then divided into population quintiles with each quintile corresponding to a level ranging from 1 (the poorest) to 5 (the richest).

Table 2.4 Wealth quintiles

Percent distribution of the de jure population by wealth quintiles, according to residence and region, Continuous DHS, Senegal 2012-2013

Residence/region	Wealth quintile					Total	Number of persons
	Lowest	Second	Middle	Fourth	Highest		
Residence							
Urban	1.2	4.8	16.7	32.9	44.3	100.0	15,378
Rural	33.1	30.5	22.3	11.0	3.1	100.0	22,139
Major region							
North	23.0	22.4	27.7	17.7	9.2	100.0	72,229
West	4.5	11.2	16.2	26.9	41.1	100.0	13,194
Center	24.3	23.7	21.8	20.1	10.1	100.0	10,108
South	39.9	28.6	16.7	9.1	5.6	100.0	6,994
Total	20.0	20.0	20.0	20.0	20.0	100.0	37,518

Overall, the results presented in Table 2.4 show that the level of wealth is lower in rural than in urban areas: only 3 percent of households fall in the “richest” or highest level of wealth in rural areas, compared with 44 percent in urban areas. By comparison, households in the lowest quintile account for 33 percent in rural areas but only 1 percent in urban areas. With regard to major regions, the West by far outranks other regions by having the highest percentage of households in the richest category (41 percent); the North and Center regions have very similar wealth levels (the North has a level of 27 percent in the “fourth” and “highest” category compared with 30 percent for the Center region). In contrast, the South region has the highest percentage of households in the lowest level (40 percent).

2.2 BACKGROUND CHARACTERISTICS OF WOMEN

Age is a fundamental variable in the analysis of demographic phenomena. It is also one of the most difficult pieces of information to obtain in a precise way, especially when the written recording of civil events, such as births, marriages, or deaths, is not yet anchored in the habits of certain populations. For these reasons, particular care was given to the collection of this information during field work. Table 2.5 shows that the distribution of women age 15-49 by five-year age groups presents a somewhat regular trend, with the proportion in each age group becoming less and less as the higher age groups are reached. They go from 23 percent for the 15-19-age group to 7 percent at age 45-49.

Questions on marital status were asked of all women age 15-49. For the Continuous DHS 2012-2013, the term union is used for all women who stated that they were married (whatever the type of marriage) or living with a partner. According to this definition, three in ten women (31 percent) are single; two-thirds (64 percent) are in union; and 5 percent are out of union (divorced, separated, or widowed).

More than half of the women (54 percent) live in rural areas. Nearly two in five women (38 percent) live in the major region of the West. About 27 percent of women live in the Center, and 19 percent live in the North. The South region has the lowest proportion of inhabitants (16 percent).

The distribution according to level of education shows that more than one in two women (55 percent) have no education, while more than one in five women (22 percent) have primary level and 23 percent have secondary level education or more. Concerning religion, 97 percent of respondents are Muslim; about 3 percent are Christian.

Table 2.5 Background characteristics of respondents

Percent distribution of women age 15-49 by selected background characteristics, Continuous DHS, Senegal 2012-2013

Background characteristic	Weighted percent	Weighted number	Unweighted number
Age group			
15-19	23.3	2,015	2,073
20-24	20.6	1,781	1,761
25-29	17.8	1,538	1,521
30-34	13.3	1,151	1,143
35-39	10.5	909	912
40-44	7.6	660	692

West	38.0	3,283	1,511
Center	27.0	2,331	2,827
South	16.2	1,403	2,404
Education			
No education	54.8	4,728	4,909
Primary	22.5	1,943	1,875
Secondary or more	22.8	1,965	1,852
Total 15-49	100.0	8,636	8,636

Note: Education categories refer to the highest level of education attended, whether or not that level was completed

With regard to the distribution of the population by ethnicity, three major groups are identified: the Wolof (39 percent), Poular (28 percent), and Serer (16 percent). They are followed by the Mandingue and Diola (4 percent each) and then by the Soninké (3 percent). Other ethnic groups and non-Senegalese represent 8 percent of women.

LIVING CONDITIONS OF CHILDREN

Papa Ibrahima Sylmang SENE and Abdoulaye GUEYE

Key Findings

- In Senegal, 73 percent of children under age 5 are recorded in the registry of civil status. This registration level has not changed measurably since the earlier EDS-MICS 2010-2011 when registration reached a high of 75 percent. In the current survey, registration of children increases with household level of wealth: from 46 percent of households in the lowest wealth quintile to 94 percent of households in the highest wealth quintile.
- In 2012-2013, 51 percent of primary-school-age children attended primary school, while only 25 percent of children of secondary school age attended secondary school. Girls of primary school age attend primary school a little more often than boys; the index of gender parity is 1.03. At the secondary level, the index is 0.99, indicating that girls of secondary school age are attending secondary school as often as boys are.
- Among children age 5-14, 15 percent are working. More boys work than girls (19 percent versus 10 percent). In addition, more rural children work than children in urban areas (20 percent versus 5 percent).
- Among children under age 18, 57 percent live with both biological parents. This situation is more common in rural areas (59 percent) than in urban areas (54 percent). In addition, 7 percent of children are fatherless, motherless, or both.

How children live in Senegal is the subject of special attention from the state, as well as numerous organizations such as the United Nations Children's Fund (UNICEF), the International Labor Organization (ILO), and other nongovernmental organizations. To better understand the living conditions of children, this chapter discusses the reporting of births to civil authorities, access to education, employment, and survival of biological parents.

3.1 REGISTRATION OF BIRTHS

Birth registration is a legal obligation in Senegal, one that is written into Article 33 of the Family Code: “Statements are to be entered in the registry within one month by the persons listed in Articles 51 and 67. If the statements of births and deaths occurring in their jurisdiction are not made within the period of one month, the neighborhood or village heads are required to report the omitted statements in the next fifteen days to the officer of civil status, subject to fines for petty offenses ranging from 2,000 to 5,000 francs.”

During the survey, respondents were asked if the births of their youngest children (under age 5) had been reported to the registrar.

The survey reveals that the majority of Senegalese children are recorded in the civil registry (73 percent, nearly three out of four children) as shown in Table 3.1. Fifty percent of children under age 5 had a birth certificate, while 24 percent did not but had been recorded in the registry. There were no significant differences by age group (48 percent of children less than age 2 and 51 percent of children age 2 to 4 are recorded in the registry and have a birth certificate) or gender (50 percent of boys and 49 percent of girls have birth certificates).

Table 3.1 Birth registration of children under age 5

Percentage of de jure children under age 5 whose births are registered with the civil authorities, according to background characteristics, Continuous DHS, Senegal 2012-2013.

Background characteristic	Children whose births are registered			
	Percentage who had birth certificate	Percentage who did not have birth certificate	Percentage registered	Number of children
Age				
<2	47.7	25.3	73.0	2,500
2-4	50.7	22.3	73.0	3,859
Sex				
Male	49.8	24.3	74.1	3,172
Female	49.2	22.6	71.9	3,188
Residence

Rural	42.3	21.4	63.7	4,230
Major region				
North	54.5	9.5	64.0	1,287
West	56.6	30.3	86.9	1,894
Center	46.2	28.9	75.1	1,953
South	38.6	18.9	57.5	1,225
Wealth quintile				
Lowest	29.0	17.0	46.0	1,566
Second	42.8	23.5	66.3	1,395
Middle	53.3	28.2	81.4	1,305
Fourth	65.7	24.9	90.6	1,062
Highest	68.3	25.8	94.1	1,031
Total	49.5	23.5	73.0	6,360

The registration of births in the registry varies widely according to major region and place of residence. Children in the civil registry who have a birth certificate are proportionally much less numerous in rural areas (42 percent) than urban areas (64 percent). At the major regional level, children in the Center (46 percent) and South (39 percent) regions are those who are the least likely to have a birth certificate; on the other hand, more than half the children in the West (57 percent) and North (55 percent) regions have been reported in the civil registry and do have a birth certificate.

The proportion of registered children may be influenced by the level of wealth of the child's household, going from 46 percent in the lowest quintile households to 94 percent in the highest quintile.

3.2 ACCESS TO EDUCATION

Access to education is considered by UNICEF to be “a key factor” for the development of children. In Senegal, Law 2004-37 of December 15, 2004, specifies in Article 3a that “education is compulsory for all children of both sexes age 6 to 16 years.” To assess the situation of children in terms of schooling, two indicators are calculated: the gross and net ratios of attendance. These indicators are calculated for both primary and secondary levels and focus on children age 6 to 16.

3.2.1 Gross Attendance Ratio

The gross attendance ratio¹ (GAR) at the primary level is the total number of pupils in primary school, expressed as a percentage of the entire population of official age for attending primary school. The gross attendance ratio at the secondary level is the total number of students in secondary school, expressed as a percentage of the entire population of official age for attending secondary school. For any given level, if there is a significant number of pupils older or younger than the official age for that level of education, the GAR may exceed 100 percent for that level.

The survey shows that 78 percent of children regardless of age are attending primary school (Table 3.2). The gross attendance ratio is influenced by the children's place of residence and the level of household wealth. Notably, the proportion of children attending primary school is much greater in urban areas (96 percent) than rural areas (68 percent). The lowest ratios were observed in the Center region (61 percent). The highest ratio was recorded in the West region (93 percent), while the North and South regions follow with 73 percent and 84 percent, respectively. The figures reveal a slight positive bias in favor of girls, with 80 percent attending compared with 76 percent for boys. This bias is more pronounced in the North region with a gender parity index of 1.2. The GAR at the primary level seems to depend on the level of household wealth. At the primary level, it is 59 percent for children from the poorest households and 99 percent for those whose households are in the wealthiest quintile.

Compared with the GAR at primary school, the ratio for children at the secondary level declines 13 percentage points, going down from 78 percent to 65 percent. It is notable that the proportion of children attending secondary school is much greater in urban areas (97 percent) than rural (45 percent). Similarly to the primary level, the GAR at the secondary level is highest in the West region (75 percent) and lowest in the Center region (49 percent). Overall, for secondary school, the GARs are higher for boys; in three out of four regions, the gender parity index is in favor of boys (less than 1). Efforts are still needed especially in the Center and South regions to keep girls in secondary school; in the South the gender parity index is 0.78. The GAR at the secondary level also seems to depend on the level of household wealth, 24 percent for children in the lowest quintile and 105 percent for those in the highest.

3.2.2 Net Attendance Ratio

The net attendance ratio (NAR) for the primary level is the percentage of the primary school age population (age 6-11) that attends primary school. The net attendance ratio for the secondary level is the percentage of secondary school age population (12-16 years) that attends secondary school. By definition, the net attendance ratio cannot exceed 100 percent.

The survey (Table 3.2) shows that 51 percent of children age 6 to 11 attend primary school. The NAR is influenced by the children's place of residence and the level of wealth of the household. The proportion of children age 6-11 who attend primary school is much greater in urban areas (66 percent) than rural areas (43 percent). The lowest ratio is observed in the Center region (36 percent). The highest ratio is recorded in the West region (60 percent); the North and South regions follow with 52 percent and 57 percent, respectively. The figures reveal a slight positive bias for girls age 6-11, with 52 percent attending school compared with 50 percent for boys of the same age. This bias is more pronounced in the North region with a gender parity index of 1.2. The NAR at the primary level seems to depend on the level of household wealth. It is 39 percent for children from the lowest quintile and 70 percent for those from the highest quintile.

¹ The gross and net attendance ratios are calculated according to the law of 2004, which makes school attendance compulsory for all children age 6 to 16.

Table 3.2 School attendance ratios

Net attendance ratios (NAR) and gross attendance ratios (GAR) for the de facto household population by sex and level of schooling; and the Gender Parity Index (GPI), according to background characteristics, Continuous DHS, Senegal 2012-2013

Total	24.6	24.4	24.5	0.99	66.9	62.8	64.8	0.94		

¹ The NAR for primary school is the percentage of the primary-school age (6-11) population that is attending primary school. The NAR for secondary school is the percentage of the secondary-school age (12-16 years) population that is attending secondary school. By definition the NAR cannot exceed 100 percent.

² The GAR for primary school is the total number of primary school students, expressed as a percentage of the official primary-school-age population. The GAR for secondary school is the total number of secondary school students, expressed as a percentage of the official secondary-school-age population. If there are significant numbers of overage and underage students at a given level of schooling, the GAR can exceed 100.0.

³ The Gender Parity Index for primary school is the ratio of the primary school NAR (GAR) for females to the NAR (GAR) for males. The Gender Parity Index for secondary school is the ratio of the secondary school NAR (GAR) for females to the NAR (GAR) for males.

At the secondary level, the NAR for children age 12 to 16 is much lower than at the primary level (25 percent versus 51 percent). Notably, the proportion of children attending secondary school is much greater in urban areas (36 percent) than rural areas (17 percent). The largest NAR is found in the North region (32 percent) while the lowest is in the Center region (17 percent). Thus, unlike the primary level where the West region has the highest level of attendance for secondary school, the North region is first in level of attendance. Overall, for secondary school, the net attendance ratios for girls and for boys are almost the same; the gender parity index is 0.99. However, efforts are still needed in the South region to keep girls in school at the secondary level where the gender parity index was .82. The net attendance ratio at the secondary level seems to

depend on the level of household wealth. It is 11 percent for children from the poorest households compared with 41 percent for those from the richest households.

3.3 CHILD LABOR

Convention 138 of the ILO sets the minimum age for accepting employment at 15. It was ratified by Senegal in 1999, while Convention 182 on the Worst Forms of Child Labor (WFCL) was ratified in 2000. The two conventions define a child as being a person under age 18. The employment acceptance age of 15 may be lowered to 12 years for light work performed within the family home that does not affect health, morals, safety, and the normal schooling of the child. This age is raised to 18 years for hazardous work.

Table 3.3 presents the percentage of children age 5-14, who, during the week preceding the interview, were involved in child labor outside the household, in the fields or in the family business, or who had performed household chores, depending on the number of hours worked, according to background characteristics.

The survey revealed that 15 percent of children age 5-14 had worked during the week preceding the interview. However, 14 percent of children age 5-11 years and 16 percent of children age 12-14 had worked during the same time period.²

In the age group 5-11 years, housework for less than 28 hours predominates (76 percent). Work in the family business and lands is also quite high (12 percent). Work outside the household at this age is very uncommon (less than 1 percent).

There is a significant variation in the proportion of children age 5-11 years who work by gender, area of residence, major region of residence, school attendance, and educational attainment of the mother. Child labor at age 5-11 years is more common in boys (19 percent versus 8 percent for girls) and in rural areas (20 percent versus 3 percent in urban areas). It is also more common for children who are not attending school (15 percent) than others (12 percent). The higher the level of education of the mother, the lower the proportion of children who work, going from 16 percent for children whose mothers are not educated to 1 percent for those whose mothers have secondary education or more. According to major region of residence, child labor is more common in the Center and South (17 percent) than in the West (11 percent). Analysis of results by level of household wealth shows that child labor is more prevalent in disadvantaged homes (29 percent in the lowest quintile compared with 2 percent in the highest quintile).

² For children age 5-11, work includes economic activity for at least 1 hour and/or housework for 28 hours or more. For children age 12-14, work involves economic activity for 14 hours or more and/or housework for 28 hours or more.

Table 3.3 Child labor

Percentage of children involved in economic activity and household chores in the week before the interview, by age group and percentage of children age 5-14 years involved in child labor, according to background characteristics, Continuous DHS, Senegal 2012/2013

Background characteristic	Percentage of children age 5-11 involved in:						Percentage of children age 12-14 involved in:

¹ For children age 5-11, economic activity for at least one hour includes economic activity outside the household (paid or not paid) and/or household chores.

² For children age 5-11, economic activity includes economic activity for at least one hour and/or household chores for 28 hours or more.

³ For children age 12-14, economic activity includes economic activity for 14 hours or more and/or domestic work for 28 hours or more.

⁴ Including 18 children age 5-14 for whom information on the educational level of the mother is missing.

For the age group 12-14, housework for less than 28 hours also predominates (81 percent). Work in the family business or on family land is also quite high (19 percent). Work outside the household at this age is very uncommon (less than 2 percent).

There is also significant variation in the proportion of working children age 12-14 by sex, place of residence, region of residence, school attendance, and mother's level of education. Child labor in the age group 12-14 is more common in boys (19 percent) than girls (14 percent) and in rural areas (21 percent) than urban (10 percent). It is also more common in children who do not attend school (30 percent) than in children who do (10 percent). As for the age group 5-11, the higher the level of education of the mother, the lower the proportion of children who work. The level goes from 19 percent for children whose mothers have no education to 1 percent for those whose mothers have secondary level education or more. Depending on the region of residence, child labor for those age 12-14 is more common in the Center (21 percent) and South (17 percent) than in the West (13 percent) and North (14 percent). Analysis of the results according to the level of household wealth shows that child labor is more prevalent among disadvantaged households (33 percent in households in the lowest quintile and 11 percent in the highest quintile).

For child labor as a whole (ages 5-14), there are also disparities by sex, area and region of residence, school attendance, and educational attainment of the mother. Child labor among those age 5-14 is, just as for the age group 12-14, more common in boys (19 percent) than girls (10 percent) and in rural areas (20 percent) than urban areas (5 percent). It is also more common in children who do not attend school (18 percent) than among those who do go to school (11 percent). Similarly, in the age groups 5-11 and 12-14, the higher the level of education of the mother, the lower the proportion of children who work; going from 16 percent for children whose mothers have no education to 1 percent for those whose mothers have a secondary level or higher. Depending on the major region of residence, child labor in the age group 5-14 is more common in the Center (18 percent) and South (17 percent) than in the West (11 percent) and North (12 percent). Finally, children from households in the lowest wealth quintile work more frequently than those from households in the highest quintile (30 percent versus 5 percent).

With regard to the results found in Table 3.4, it can be seen that the involvement of children age 5-14 years in economic and domestic activities has a significant impact on their level of school attendance. Indeed, the ratio of school attendance among children who are working (40 percent) is lower than that for children age 5-14 years overall (52 percent).

School attendance of children age 5-14 years also has an impact on child labor since, among children who are attending school, 11 percent work compared to 15 percent for all children age 5-14 years.

The highest school attendance was observed among children age 12-14 years (68 percent), female gender (53 percent), children from urban areas (67 percent), those from the West region (62 percent), those whose mothers have a secondary level of education or more (79 percent) and children belonging to the highest wealth quintile (72 percent). Among children who are working, those who most often go to school are female (44 percent), children from urban areas (70 percent), those from the West region (59 percent), those whose mothers have primary education (59 percent), and children belonging to the wealthiest quintile (82 percent). On the other hand, among children who attend school, those who are most often working are males (15 percent), children from rural areas (17 percent), those from the South (15 percent) and East (14 percent) regions, those whose mothers have no education (13 percent), and children belonging to the lowest wealth quintile (22 percent).

Table 3.4 Child labor and school attendance

Percentage of children age 5-14 involved in child labor and percentage attending school; among children age 5-14 who are working, percentage who are attending school, and among children age 5-14 who are attending school, percentage who are working, according to background characteristics, Continuous DHS, Senegal 2012-2013

3.4 CHILDREN LIVING APART FROM THEIR BIOLOGICAL PARENTS AND ORPHANHOOD

In Senegal, as in many African countries, society and the family play an important role in the survival and development of children. It is therefore essential to identify children who are separated from their biological parents and know with whom they live. Table 3.5 presents this information for children under age 18.

The survey reveals that 15 percent of children live with neither biological parent and that 57 percent of children under the age of 18 live with both biological parents. The proportion of children living with no biological parent is very high for children over the age of 10 (20 percent for 10-14 year olds and 32 percent for those age 15-17 years) but also remains high for those under 9 years of age. It is also relatively higher for girls (17 percent) than for boys (13 percent).

Among children living with their biological parents, age plays a crucial role. Indeed, the proportion of children living with their biological parents decreases steadily with the age of the child. From a peak of 62 percent under the age of 2 years, the proportion goes to 59 percent at 5-9 years and reaches 43 percent at 15-17 years. Girls are slightly less likely (56 percent) than boys (58 percent) to be living with both parents. Among children under the age of 18, 26 percent live only with their mother, whether the father is alive (22 percent) or deceased (3 percent). About 3 percent are living only with their father, whether their mother is alive (2 percent) or not (1 percent), while 15 percent do not live with either of their parents.

Table 3.5 Children's living arrangements and orphanhood

Percent distribution of de jure children under 18 by living arrangements and survival status of parents, the percentage of children not living with a biological parent, and the percentage of children with one or both parents dead, according to background characteristics, Continuous DHS, 2012-2013

Note: Table is based on de jure members, i.e., usual residents.

¹ Includes children with father dead, mother dead, both dead, and one parent dead but missing information on survival status of the other parent.

Place of residence and level of wealth seem to be important determinants of the situation of children. The proportion of children living with both parents is slightly higher in rural areas (59 percent) than in urban areas (54 percent). There are considerable differences between the major regions of the country: in the regions of the West (54 percent) and North (55 percent), the proportion of children living with both their parents is lowest, and in the Center region it is highest (68 percent). The proportion of children living with both parents decreases with the level of household wealth up to the fourth quintile. It is highest among children living in households in the lowest quintile (72 percent) and lowest among those living in households in the fourth quintile (47 percent).

The survey also shows that the proportion of children under 18 who are orphaned by their father and/or mother is 7 percent. Less than one percent (0.4 percent) have lost both parents; 5 percent are orphans through their father (3 percent where the father is deceased and the children live with their mother and 2 percent where the father is deceased and the children do not live with their mother) and 2 percent are orphans through their mother (1 percent where the mother is deceased and the children are living with their father and 1 percent where the mother is deceased and the children are not living with their father).

Because of the increased risk of parents dying linked to the child's age, the proportion of fatherless and/or motherless orphans and of children living with neither biological parent significantly increases with the age of the child. The proportion of fatherless and or motherless orphans goes from 1 percent under the age of 2 to 2 percent at 2-4 years and 19 percent at 15-17 years, while the proportion of children not living with either parent goes from 6% percent under age 2 to 9 percent at 2-4 and to 31 percent at 15-17. Sex, place of residence, and level of household wealth do not seem to influence the risk of a child being orphaned; the same is true for the proportion of children not living with any biological parent.

FERTILITY AND CHILD MORTALITY

Cheikh Tidiane NDIAYE

Key Findings

- The fertility of women in Senegal declined steadily from 1986 to 2010-2011, with the number of children born to each woman dropping from 6.4 to 5.0. The Continuous DHS estimates the current fertility level to be 5.3 children per woman, slightly higher than the previous survey; however, this difference was not statistically significant.
- Very notable differences in fertility appear between areas of residence; an urban woman has a significantly lower level of fertility (4.1 children per woman) than a rural woman (6.3).
- Infant and child mortality remains high nationally. For the most recent period (0-4 years before the survey) of 1,000 live births, 47 infants died before their first birthday. Among every 1,000 one-year-old children, 23 will not reach their fifth birthday. Overall, the risk of dying between birth and the fifth birthday is 65 per 1,000 births, about one child in 15.
- The level of child mortality has declined steadily over the last 15 years. From 10-14 years before the Continuous DHS was conducted, infant and child mortality was 121 per 1,000 births compared with only 65 per 1,000 births for the period 0-4 years before the survey.

As in previous Demographic and Health Surveys, in the 2012-2013 Continuous DHS, information was collected on the reproductive history of women to estimate fertility levels, identify trends, and assess any differences among socioeconomic groups. To this end, the interviewers asked all women age 15-49 in the selected households the total number of live births they had had, both for those children living with them as well as for those living elsewhere and those who had died. Then, the complete birth history of the respondent was taken, from the earliest to the most recent, recording for each the type of birth (simple or multiple), sex, date of birth, and current age for living children. The birth history thus allows the estimation of child mortality levels in addition to fertility levels.

The levels of child mortality and their variability depend, regardless of the affected population, on health and environmental and socioeconomic conditions that prevail in their global context. Despite enormous advances in modern medicine, the risk of dying before or during childbirth, but also during the first days, months, and years of life remains important. Thus, this chapter presents the dynamics of mortality in children before their fifth birthday from questions on the age at death of children.

4.1 FERTILITY

4.1.1 Methodological Considerations

The data collected are used to estimate not only the level of fertility in the current period but also trends in fertility during the 20 years preceding the survey. However, it is worth mentioning the following limitations of retrospective surveys:

- Underreporting of births, especially the omission of very young children; children who do not live with their mother; and children who die very young, several hours or days only after birth. This underreporting may result in an underestimation of fertility levels.
- Inaccuracy of statements about the date of birth and/or age, in particular, the attraction of rounded years of birth or ages, which could lead to underestimates or overestimates of fertility at certain ages and for certain periods of time
- Selective bias of survival, the women interviewed being those who are the survivors. Assuming that the fertility of women who died before the survey is different from that of the survivors, the fertility levels obtained may be slightly biased.

The information may also be affected by misclassification of birth dates for children born since January 2007; those dates may have been transferred to previous years. These birth year transfers found in most DHS-type surveys are sometimes carried out by interviewers in order to avoid asking questions about the health of children born since 2007. However, no significant underreporting or transfers that could significantly affect current fertility levels have been identified.

4.1.2 Level of Fertility and Differential Fertility

The level of fertility is measured by age-specific fertility rates and by total fertility rate (TFR). Fertility rates by age are calculated by linking births to women in each age group to the total number of women in the corresponding age group. The TFR, which is a trend indicator of fertility, is obtained from the cumulative fertility rates by age. It corresponds to the average number of children that would be born per woman by the end of her reproductive life if the fertility rates of the moment remained invariable. For current fertility, the fertility rates and the TFR were calculated for the period three years preceding the survey. This reference period of three years has been chosen in order to provide the most recent indicators of fertility possible while still having enough cases to reduce sampling errors.

Table 4.1, illustrated in Figure 4.1, shows that fertility rates by age follow a classic pattern generally observed in countries with high fertility: high early fertility (80 per thousand at age 15-19), which increases very rapidly and reaches its maximum at age 25-29 (246 per thousand) and which, thereafter, decreases steadily to 19 per thousand at 45-49. Overall, the fertility of Senegalese women still remains high, with a woman giving birth, on average, to 5.3 children by the end of her reproductive life. The overall general fertility rate (GFR), that is, the average annual number of live births in the population of women of childbearing age, and the crude birth rate (CBR), which is the ratio between the number of live births and the average population in that year, are estimated at 172 per thousand and 39 per thousand, respectively.

Table 4.1 Current fertility

Age-specific and total fertility rates, the general fertility rate, and the crude birth rate for the three years preceding the survey, by residence, Continuous DHS, Senegal 2012-2013

Age group	Residence		
	Urban	Rural	Total
15-19	43	110	80
20-24	156	258	210
25-29	190	294	246
30-34	189	254	223
35-39	156	207	184
40-44	75	116	97
45-49	9	29	19
TFR (15-49)	4.1	6.3	5.3
GFR	131	207	172
CBR	32.9	42.7	38.6

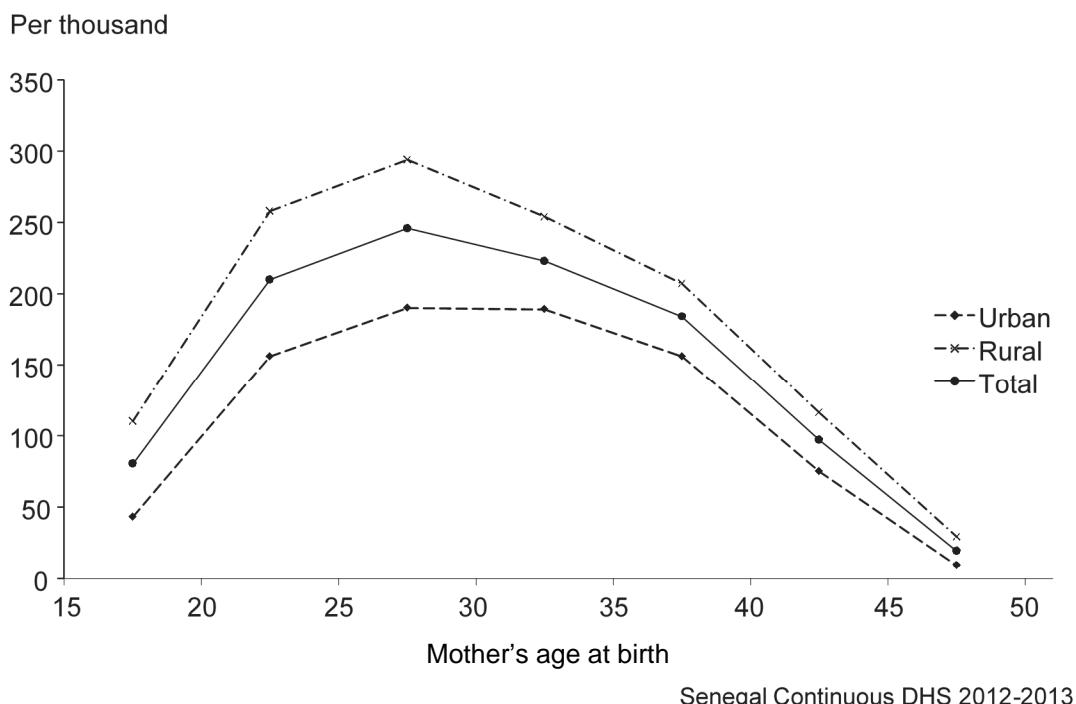

Notes: Age-specific fertility rates are per 1,000 women. Rates for age group 45-49 may be slightly biased due to truncation. Rates are for the period 1-36 months prior to interview.

TFR: Total fertility rate expressed per woman

GFR: General fertility rate expressed per 1,000 women age 15-44

CBR: Crude birth rate expressed per 1,000 population

Figure 4.1 Age-specific fertility rates, according to residence

This overall fertility level masks significant disparities according to place of residence. Fertility is significantly lower in urban areas than in rural (TFR of 4.1 versus 6.0). At the end of their reproductive life, rural women give birth, on average, to two children more than those in urban areas. This difference in fertility levels between urban and rural areas is observed at all ages, especially among teenage girls under Rural teenagers are more than twice as fertile as those in urban areas.

4.1.3 Fertility Trends

Senegal has carried out five DHS surveys over the past 25 years. A main objective was to assess trends in fertility (Table 4.2 and Figure 4.2).

Over time, the total fertility rate has declined slowly but steadily from 6.4 children per woman in 1986 to 6.0 in 1992, 5.7 in 1997, 5.3 in 2005 and, finally, to 5.0 in 2011. According to the Continuous DHS, the TFR level is at 5.3 children per woman, slightly higher than the estimated TFR in 2010-2011. However, the difference between these two levels is not statistically significant and, thus, a change in direction toward increased fertility cannot be concluded. In addition, the six curves in have a similar look and follow the classic pattern of evolution in fertility rates. In fact, childbearing occurs very early at age 15-19, increases quite rapidly to a peak at 25-29 years, and then declines steadily. In 2012-2013, except for age group 15-19, the age-specific rates are slightly higher than in 2010-2011, but again, none of these differences were statistically significant.

Table 4.2 Trends in age-specific and total fertility rates

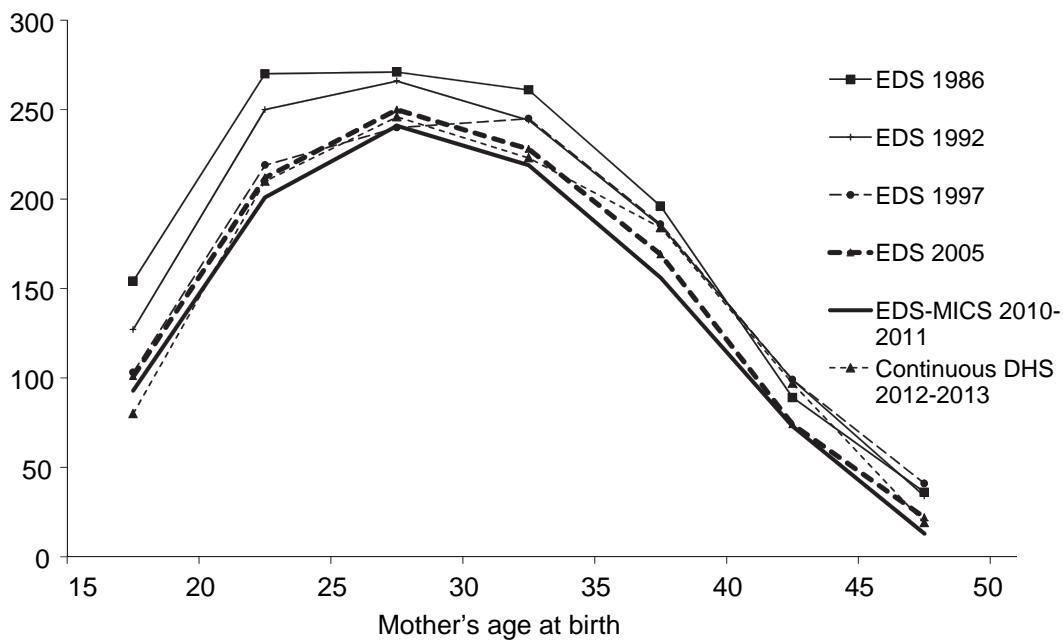

Age-specific and total fertility rates (TFR) for the three-year period preceding several surveys

Age group	EDS 1986	EDS 1992	EDS 1997	EDS 2005	EDS-MICS 2010-11	Continuous DHS 2012-2013

Per thousand

4.2 CHILD MORTALITY

4.2.1 Methodology and Data Quality

Mortality indicators in this chapter are estimated from the birth history in the Woman's Questionnaire. In addition to a list of all births that a woman has had, the interviewer collected information on each birth such as gender, age, survival status, and age at death for deceased children. Because of its importance for the extent of the phenomenon, the age at death was collected to the day of death for deaths of less than one month, in months for those between one month and 23 months, and in years for deaths occurring at two or more years.

The indicators discussed in this chapter are defined below:

The ratio of neonatal mortality (NN): probability of dying before reaching the age of one exact month

The ratio of post-neonatal mortality (PNN): probability of dying between the 1st month and the 12th exact month

The ratio of infant mortality ($1q_0$): probability of dying between birth and the first birthday

The ratio of child mortality ($4q_1$): probability of dying between the first and fifth birthday

The ratio of infant and child mortality ($5q_0$): probability of dying between birth and the fifth birthday

Methodological limitations

The methodology used to estimate child mortality has some limitations. These limitations, as well as some risk of error inherent in recording, can affect the quality of the estimates to a certain extent.

One of the weaknesses of the methodology used in the survey is its limit on data collection only to women age 15-49 who are alive at the time of the interview while excluding information about the survival status of children whose mothers were deceased before the survey. Indeed, the estimated overall level of mortality could be slightly biased if the number of motherless children is relatively large, and if the mortality of these orphans is substantially different than that of children whose mothers were interviewed in the survey.

In addition, by limiting data collection to women age 15-49 at the time of the survey, information derived from birth histories is not completely representative for some past periods. For the period 10-14 years before the survey, for example, no information is available on births to women age 40-49 at that time. Women age 15-49 at the time of the survey were under 40 ten years before the survey, and those age 40-49 at that time were no longer eligible at the moment of the survey. Therefore, if a significant proportion of births from that time were from women age 40-49 and if the risk of dying for their children was very different from that for births from younger women, a significant bias could result in the estimation of mortality for the period studied.

Overall, the effect of these phenomena is not a serious bias; the percentage of maternal orphans is relatively low, and women 40 and older who are reaching the end of their reproductive life contribute little to overall fertility.

Risk of reporting error

The validity of data on child mortality can be affected by many factors.

- The underreporting of events may result from systematic omission of births and/or deaths, which leads to an underestimation of mortality. Omission of births generally occurs when the child dies very young, that is, a few hours/days after birth. In such cases, the further away the reference period is from the date of the survey, the greater is the risk of omissions and the higher is the underestimation of mortality levels. The evaluation of underreporting of deaths of very young children is made by comparing deaths of children who died between 0 and 6 days with deaths that occurred during the first month of life. This proportion increases with decreasing child mortality because the mortality level decreases very rapidly between birth and the days that follow. A proportion of early deaths lower than 60 percent would indicate significant underreporting of early deaths. In the case of the 2012-2013 Continuous DHS, this proportion is 69 percent (data not shown) indicating that there was no significant underreporting of early deaths during the five years preceding the survey.
- The transfer of dates of birth of children from one period to another can cause an underestimation of mortality for one period in favor of overestimation in adjacent periods. Thus, misclassification of deaths in the 0-4 year interval before the survey would result in an underestimation of mortality for this period and an overestimation in the preceding interval, 5-9 years before the survey. Again, data from the Continuous DHS (data not shown) do not show significant transfers from one five-year period to another, which could affect estimates of mortality levels in a significant way.
- The inaccuracy of statements of age at death, like the attraction of certain ages at death, can lead to an underestimation of infant mortality and an overestimation of child mortality by the transfer of a portion of the deaths of children under age 1 to the category of deaths of older children. To minimize this type of error, age at death was reported in days, months, or years, depending on whether the death occurred within 29 days after birth, between 1 and 23 months, or over 23 months, respectively. However, the data collected show no attraction for the age at death of “12 months” and therefore estimates of infant mortality and child mortality are not affected.

4.2.2 Levels and Trends

The various mortality rates for the 15 years preceding the survey are presented in Table 4.3. Levels are calculated by five-year periods of 0-4 years, 5-9 years, and 10-14 years before the survey, from 1998 to 2013.

In the period 2008-2013, 0-4 years before the survey, 43 children born alive out of 1,000 died before reaching their first birthday, with 26 dying between 0 and 1 exact month and 17 dying between 1 and 12 exact months. Among children over age 1, 23 per 1,000 births did not reach their fifth birthday. During this same period, the overall risk of dying between birth and the fifth birthday is estimated at 65 in 1,000 births.

The downward trend in child mortality, already observed for several years, seems to be continuing. A review of the evolution of child mortality over the past 15 years shows that, regardless of the type of mortality,

Table 4.3 Early childhood mortality rates

Neonatal, post-neonatal, infant, child, and under-five mortality rates for five year periods preceding the survey, Continuous DHS 2010-2013

Years preceding the survey	Neonatal mortality (NN)	Post-neonatal mortality (PNN) ¹	Infant mortality (1q0)	Child mortality (4q1)	Under-5 mortality (5q0)
0-4	26	17	43	23	65
5-9	36	20	56	30	84
10-14	31	32	64	62	121

¹ Computed as the difference between the infant and neonatal mortality rates.

the level fell significantly during the period. Thus, from 64 per 1,000 births in the period 10-14 years before the survey, the infant mortality dropped to 43 per 1,000 births in the period 0-4 years (last five years), for an overall decrease of 33 percent. However, this decline is not uniform throughout the period: it was nearly twice as high between 2008 and 2013 (23 percent) as it was between 2004 and 2008 (13 percent). The decline in child mortality also continues to decrease: the rate went from 62 per 1,000 children to 23 per 1,000 children, for a drop of 63 percent. However, unlike infant mortality, the decline appears to be less pronounced in the last period than in the previous period (23 percent between 2008 and 2013 versus 52 percent between 2004 and 2008). With regard to child mortality, the decline follows the same trends and is at medium levels: the overall rate went from 121 per 1,000 to 65 per 1,000, a drop of 46 percent with a smaller decrease in the recent period (23 percent between 2008 and 2013 compared to 31 percent between 2004-2008).

It should be noted that among the components of infant mortality, postnatal mortality showed a much greater decrease than neonatal mortality (47 per 1,000 versus 16 per 1,000).

Figures 4.3 and 4.4 present the trends in infant and child mortality according to the EDS-MICS of 2010-2011 and the Continuous DHS of 2012-2013. The graphs show the consistency in results from the two surveys and highlight, once again, the steady decline in infant and child mortality over the past 15 years.

Figure 4.3 Infant mortality trends according to EDS-MICS 2010-11 and Continuous DHS 2012-2013

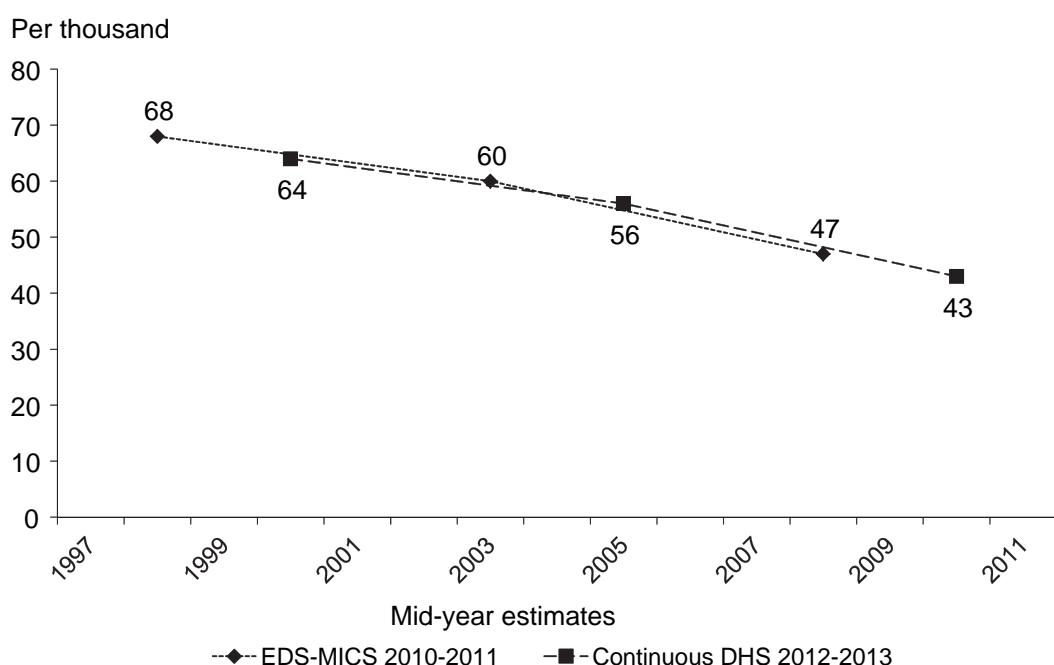

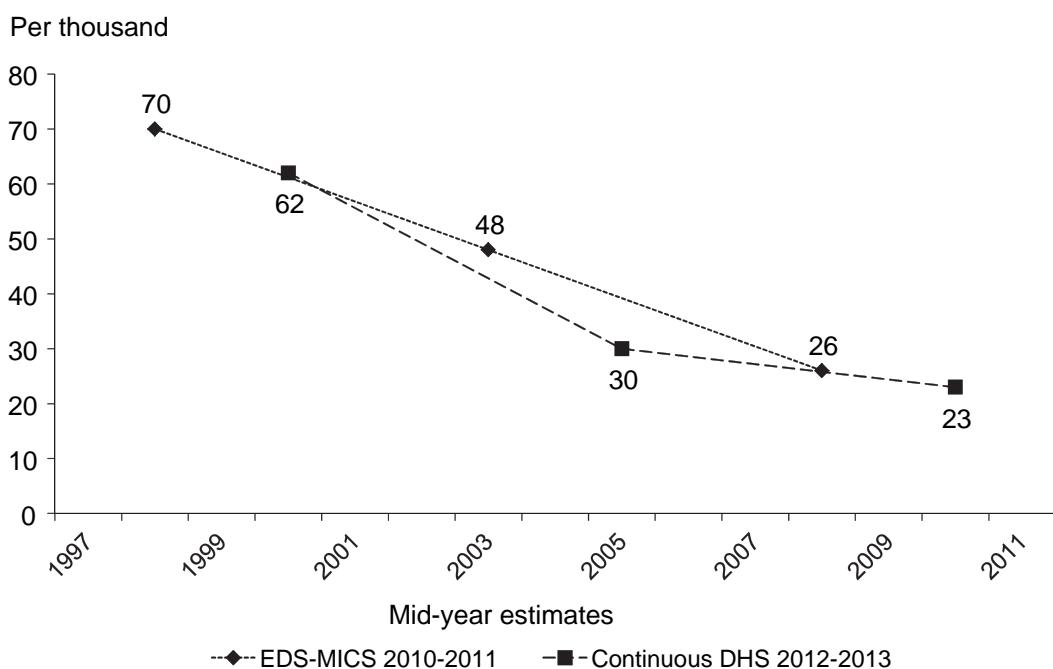

Figure 4.4 Child mortality trends according to EDS-MICS 2010-11 and Continuous DHS 2012-2013

Key Findings

- The use of contraceptive methods by married women continues to increase: 16 percent of married women use a modern method compared with 12 percent in the EDS-MICS 2010-2011.
- The use of modern methods remains practiced primarily by urban women (27 percent), those living in West region (27 percent), and women with a secondary or higher level of education (30 percent).
- In all, 66 percent of women can be considered potential candidates for family planning because they either do not want any more children (21 percent) or want to space their next child after a period of at least two years (45 percent).

In African countries, the high rate of population growth is a major constraint on development. The persistent imbalance between population growth and economic growth contributes to deterioration of household living conditions. Although fertility rates in sub-Saharan Africa are among the highest in the world, they vary in diverse situations. Demographic data has been collected since the 1970s, and knowledge of the evolution of fertility has improved significantly since then. In addition to persistent disparities between regions and countries, surveys show there are also differences in fertility between urban and rural areas of residence, with the latter often being associated with higher fertility. But beyond this dichotomy, certain characteristics of the population are more significant than others. One of the factors contributing to a recent decline in fertility observed in countries that have carried out Demographic and Health Surveys (DHS) is the practice of contraception. During recent decades, there has been a rapid and significant increase worldwide in the use of contraception.

5.1 CURRENT USE OF CONTRACEPTION

The level of contraceptive use is one of the indicators used to judge the success of family planning programs. The Continuous DHS 2012-2013 measures the level of contraceptive use at the time of the survey. Women who reported knowing a contraceptive method were asked if they used one at the time of the survey.

Table 5.1 shows the rate of contraceptive prevalence, that is, the proportion of currently married women using a contraceptive method at the time of the survey.

Overall, 18 percent of women in union are currently using a contraceptive method; 16 percent used a modern method, and less than 2 percent use a traditional method. Women mainly use injectables (6 percent) and the pill (5 percent), followed to a lesser extent by implants (3 percent) (Figure 5.1). All other methods affect less than 1 percent of respondents. Among traditional methods, periodic abstinence/rhythm is the most utilized; however, only 0.5 percent of all women age 15-49 in union use this method to plan their pregnancies.

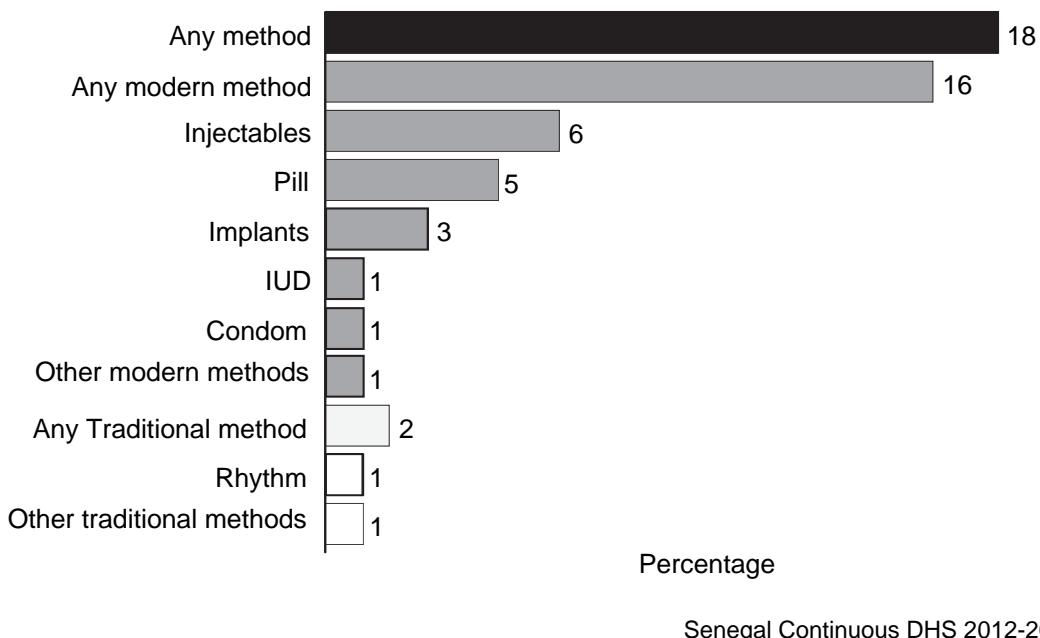

Table 5.1 Current use of contraception, by background characteristics

Percent distribution of currently married women age 15-49 by contraceptive method currently used, according to background characteristics, Continuous DHS, Senegal 2012-2013

LAM = Lactational amenorrhea method

Figure 5.1 Contraceptive prevalence among women in union by method

In addition, information collected also allows analysis of contraceptive prevalence by background characteristics of women in union (Table 5.1). The use of contraception increases steadily with age from 15 to 39 years. It is at age 35-39 years that the highest percentage of users of contraceptive methods (26 percent) is found. Contraceptive prevalence for all methods is almost three times higher in urban areas (29 percent) than in rural areas 11 percent. Among all women, the modern methods most commonly used are injectables (9 percent in urban areas and 5 percent in rural areas), the pill (9 percent in urban areas versus 3 percent in rural), and implants (5 percent in urban areas versus 1 percent in rural). The main traditional method is periodic abstinence/rhythm, which was more often used by urban women (0.9 percent) compared to rural women (0.3 percent). The differences in contraception use observed between regions are significant. The two major regions—South (9 percent) and Center (10 percent)—are characterized by a low prevalence of modern contraception. In contrast, the West region recorded the highest contraceptive prevalence rate (27 percent). In the North, the prevalence is 13 percent.

The use of contraception increases with the level of wealth of the household; for modern methods, it goes from 6 percent among women from households in the lowest quintile to 30 percent for women in the highest quintile.

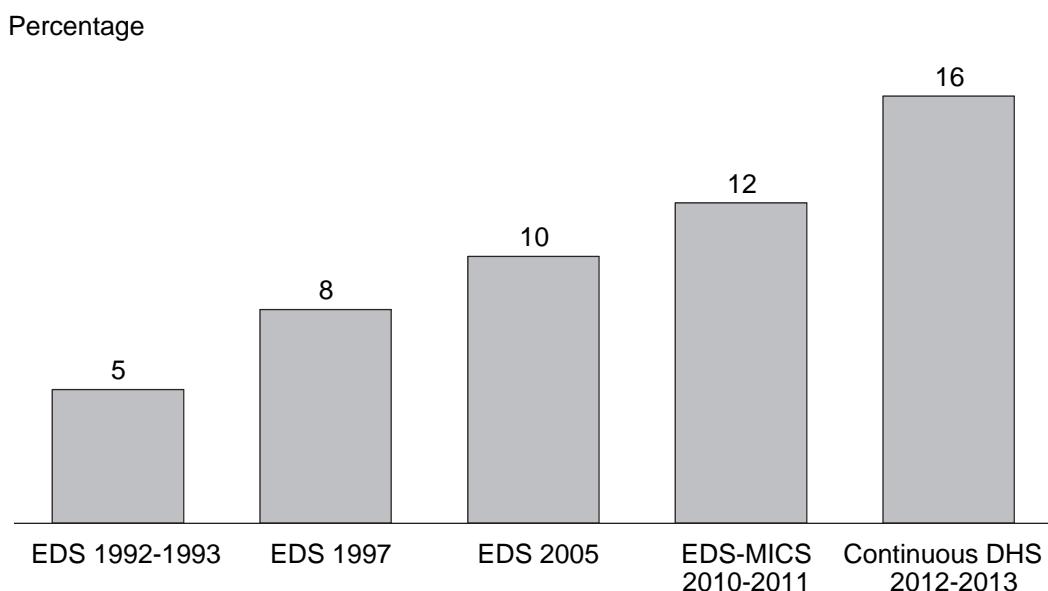

Contraceptive prevalence, whether modern or traditional, increases very markedly with the level of instruction. For modern methods, prevalence increased from 12 percent among women with no education to 24 percent among those with a primary level of education and 29 percent for women with a secondary or higher level. In addition, regardless of the level of education, injectables and the pill remain the most common modern methods.

The use of modern contraceptive methods also increases with the number of children, from 3 percent in nulliparous women, to 20 percent among those with three or more children.

Trends

Comparison with the results from previous surveys shows that modern contraceptive prevalence among married women is steadily increasing, with the proportion of users rising from 5 percent in 1992-1993 (EDSII) to 8 percent in 1997 (EDS-III), to 10 percent in 2005 (EDSIV), and to 12 percent in 2011 (EDS-MICS 2010-2011), before reaching 16 percent in 2013 (Figure 5.2). This progression has been most notable among women from rural areas and those with no education. Indeed, modern contraceptive prevalence has increased considerably in rural areas: from 1 percent in 1993, to 4 percent in 1997, 5 percent in 2005, and 7 percent in 2011 (EDS-MICS 2010-2011), and currently at 9 percent. According to level of education, the proportion of uneducated women using a modern method has doubled between 1993 and 1997, rising from 2 percent to 4 percent. The upward trend in the prevalence rate continued slowly; between 1997 and 2005, the proportion of users increased from 4 percent to 5 percent, but between 2005 and 2011, it rose from 5 percent to 8 percent and is 12 percent currently. It is also noteworthy that among women with a primary education, the rate of contraceptive prevalence increased significantly from 20 percent to 24 percent. Among those with secondary education or more, the prevalence of modern methods has gone from 26 percent in 2011 to 29 percent currently.

Figure 5.2 Trends in modern contraceptive prevalence among women in union

5.2 DESIRE FOR MORE CHILDREN

Questions were asked of women currently in union age 15-49 to obtain information on their desire to have or not have (more) children and to space their next birth. The desire to have more children is generally related to the age of the woman and the number of children currently alive. Table 5.2 and Figure 5.3 present the results by number of living children and show that one in five women (21 percent) does not want more children, while three of four women (75 percent) do want to have another child.

These results also show that among the 75 percent of women who wish to have more children in the future, almost one in two women (45 percent) wants to space the next birth by two or more years. Thus, by bringing together those who do not want more children (21 percent) and those who want to space the birth of their next child by a period of at least two years (45 percent), in all, 66 percent of women can be considered potential candidates for family planning. These levels are similar to those recorded in previous surveys: EDS-II in 1992-1993 (20 percent for those who wished to limit and 39 percent for those who wanted to space at least two years), EDS-III in 1997 (23 percent and 39 percent), EDS-IV in 2005 (21 percent and 38 percent), and EDS-MICS 2010-2011 (22 percent and 38 percent).

¹ The number of living children includes the current pregnancy.

² Wants next birth within two years

³ Wants to delay next birth for two or more years

⁴ Includes both female and male sterilization

Figure 5.3 Fertility preferences among currently married according to the number of living children

As might be expected, the proportion of women who want no more children regularly increases with the number of living children: it goes from less than 1 percent of women who have no children to 9 percent for those who have three children, and to 65 percent among those who have at least six children.

It is also notable that almost all nulliparous women (98 percent) want to have a child, and the vast majority (75 percent) want a birth in the next two years. Although almost all primiparas also want another child (98 percent), for the most part, they want to wait at least two years before the birth of the next child (64 percent).

Table C.8 in Appendix C presents the need for family planning among women currently in union.

Fatou Bintou NIANG and Cheikh Tidiane NDIAYE

Key Findings

- The vast majority of women (95 percent) consulted a health professional during pregnancy before their most recent birth.
- Seven of ten births (71 percent) took place in a health facility, and fifty percent of these births received assistance from health personnel during delivery.
- The majority (70 percent) of children age 12-23 months have received all vaccines of the Expanded Program on Immunization: BCG (96 percent), penta (3 doses, 89 percent), polio (83 percent), and measles (79 percent). During the two weeks before the survey, 3 percent of children showed symptoms of acute respiratory infection; 17 percent had a fever; and 14 percent had diarrhea.
- During diarrheal episodes, 22 percent of children received oral rehydration therapy (ORT), oral rehydration solutions (ORS), or a solution prepared at home.

The 2013 Continuous DHS collected detailed information on the health of the mother and child. This information concerns antenatal care and delivery in a health facility; immunization coverage of children age 12-23 months; and the prevalence and treatment of acute respiratory infections (ARIs), fever, and diarrhea in children under age 5. This information is of great importance for the evaluation and planning of health policies and programs.

6.1 MATERNAL HEALTH

6.1.1 Antenatal Care

Medical surveillance during pregnancy has a significant influence on the health of women and children. Prenatal care can detect complications that may endanger the lives of both mother and child. At least four antenatal visits are recommended to ensure proper monitoring over the course of the pregnancy. Antenatal clinics provide an opportunity to immunize the mother against tetanus; give her advice; and, if necessary, administer nutritional supplements at signs of malnutrition.

The data in Table 6.1 show that for women age 15-49 who had a live birth in the five years preceding the survey, the percentage of those who received antenatal care for the last live birth, at least once, from a trained provider;¹ the percentage whose last live birth was protected against neonatal tetanus, and the percentage who received iron supplements during the last pregnancy. Table 6.1 also covers all live births in the five years preceding the survey and shows the percentage of those whose birth was delivered by a trained provider and the percentage of those whose birth took place in a health facility.

¹ Table C.9 in Appendix C presents the number of antenatal visits and the stage of pregnancy.

During the Continuous DHS all categories of persons consulted by the mother during pregnancy were recorded. When several people had been consulted by the same woman, only the most qualified was counted in Table 6.1. For the last live birth during the past five years, more than nine out of ten women (94 percent) went to antenatal consultations with health professionals (doctors, midwives, nurses, or unit head nurses [UHNs]).

Table 6.1 Indicators of maternal health

Among women age 15-49 who had a live birth in the five years preceding the survey, the percentage who received antenatal care (ANC) from a health professional for the last live birth, the percentage whose last live birth was protected against neonatal tetanus, and the percentage who took iron supplements during their last pregnancy; among all live births in the five years before the survey, the percentage delivered by a health professional and the percentage delivered in a health facility, by background characteristics, Continuous DHS, Senegal 2012-2013

Background characteristic	Percentage who received antenatal care (ANC) from a health professional ¹	Percentage whose last live birth was protected against neonatal tetanus ²	Percentage who took iron supplements during pregnancy for their last birth	Number of women	Percentage of births delivered by a health professional	Percentage of births delivered in a health facility	Number of births

Total	94.5	81.8	93	4,200	50.5	71.3	6,391

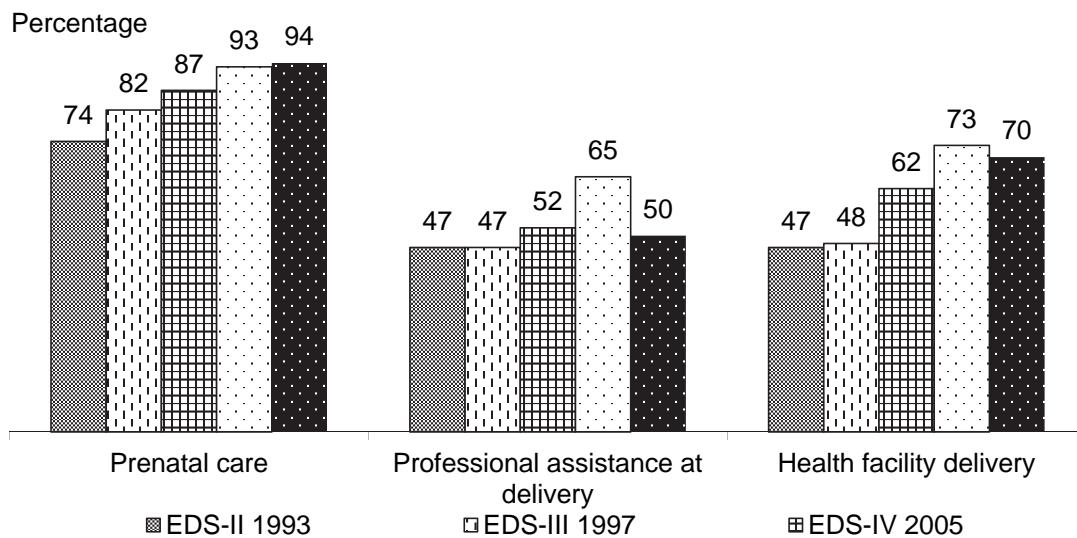

¹ Health professional includes doctor, nurse, midwife, and unit head nurse (*Infirmier chef de poste - ICP*).

² Includes mothers with two injections during the pregnancy of the last birth, two or more injections (the last within 3 years of the last live birth), three or more injections (the last within 5 years of the last birth), four or more injections (the last within 10 years of the last live birth), or five or more injections at any time prior to the last birth.

Antenatal care use differences based on age of the woman are small: 95 percent of women under age 35 and 92 percent for those whose age equals or exceeds age 35. Women from urban areas are relatively more likely (99 percent) than rural women (92 percent) to receive antenatal visits during their pregnancy. From a regional perspective, slight differences also appear: women who have least frequently consulted a health professional during their pregnancy are those from the South (90 percent) followed by those from the Center (93 percent). The proportion of births to mothers who received antenatal care from trained personnel varies depending on the level of household wealth: from 85 percent for women from households in the lowest quintile to 99 percent for women from the highest quintiles. In addition, the proportion increases with the woman's level of education: 93 percent for those with no education, 98 percent for those with primary level, and 99 percent for those with secondary education or more.

Compared with previous surveys (Figure 6.1), the proportion of women who received antenatal care from a health professional has increased from 74 percent in 1993 to 82 percent in 1997, 87 percent in 2005, 93 percent in 2010-2011, and 95 percent in 2012-2013.

Figure 6.1 Prenatal care, professional assistance at delivery, and health facility delivery

Tetanus immunization and iron intake during pregnancy are important components of antenatal care.

Neonatal tetanus is one of the most serious diseases to which the newborn can be exposed. To cope with this disease, it is recommended that pregnant women be vaccinated against tetanus. The data in Table 6.1 show that for 82 percent of women, the live birth is protected against neonatal tetanus. It is important to note that the information presented here have taken into account the vaccination history of the women. Mothers are regarded as protecting their children against neonatal tetanus if they received two injections during the pregnancy of their last birth, at least the last of two injections was given during the three years preceding the last live birth, at least three injections (the last conducted during the 10 years preceding the last live birth), or at least five injections at any time prior to the last birth. Depending on the age of the mother, birth mothers age 20-34 years are observed to be more often protected against tetanus (83 percent) than mothers under the age of 20 or those 35 years or more. With regard to place of residence, births that occurred in urban areas were better protected than those that took place in rural areas (87 percent versus 79 percent). Between regions, the vaccination status of mothers is lower in the large Center region (78 percent) than in the three other major regions (ranging between 83 percent and 84 percent). Moreover, the frequency of vaccination increases with the educational level of the mother from a minimum of 80 percent among uneducated women, rising to 85 percent for those with primary education, and reaching 86 percent for women with secondary level.

Compared with the results of the EDS-MICS 2010-2011, immunization coverage against neonatal tetanus has shown a significant increase of 19 percent, going from 69 percent to 82 percent.

In addition, during pregnancy, more than 9 out of 10 women have received iron supplements in tablet or syrup form (93 percent). Women under 35 benefited more often (at least 93 percent) than those age 35 or older (90 percent). Moreover, women in rural areas benefited less frequently than urban women (91 percent versus 97 percent). Between regions, mothers residing in the South region received iron less frequently than those from other regions (89 percent compared with 92 percent or more). The level of education is a determinant of iron intake during pregnancy: 91 percent of women with no education took supplements compared with 96 percent of those with primary education and 98 percent of those with a secondary level of education. In addition, the proportion of women who received iron increases with the index of household

wealth, from a minimum of 84 percent for women living in households in the lowest quintile of wealth to a maximum of 97 percent for those from the highest quintiles.

6.1.2 Assistance at Delivery

Good care at delivery, a key element in the fight against maternal morbidity and mortality, depends on the qualifications of persons assisting the woman. Half of all births took place with the assistance of skilled health personnel (Table 6.1), namely doctors, midwives, nurses, or UHNs.

Between the last two surveys, the proportion of births attended by trained health personnel seems to have decreased from 65 percent in 2010-2011 to 51 percent in 2012-2013 (Figure 6.1). This drop is surprising because the proportion of women assisted at delivery by trained personnel had increased steadily since 1997. The proportion of deliveries in a health facility also has changed little since 2011 (see Figure 6.1). Data differentiated by type of health personnel show that the proportion of deliveries attended by midwives has declined significantly between the two surveys, from 54 percent to 36 percent, while on the other hand, deliveries attended by traditional birth attendants have increased greatly, rising from 12 percent to 25 percent. It is difficult to explain such a radical change in the respective roles of traditional birth attendants and midwives during the two years between the two surveys. Therefore, it is possible that this change is only superficial. In fact, it may result from a difference in classification of these personnel by the interviewers during the data collection process. It is advisable, therefore, to be very cautious when interpreting this indicator and, in particular, the analysis of trends.

The percentage of births attended by a health professional varies little by age of the mother. However, a significant difference was observed between urban and rural women in childbirth assistance by trained personnel: the proportion receiving assistance in urban areas is more than double that in rural areas (78 percent versus 36 percent). In addition, the results highlight regional disparities. The best situation is in the West (68 percent) and North (51 percent), while the Center and South have a less advantageous position, since only 4 out of 10 births are attended by a health professional (respectively, 40 percent and 39 percent).

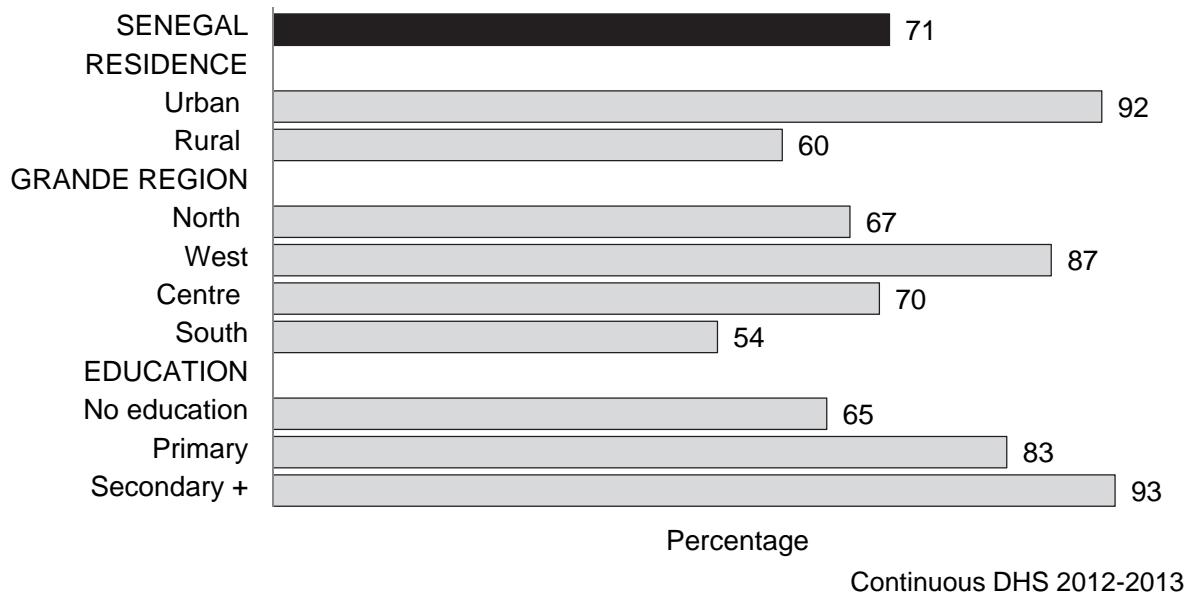

Assistance at delivery by trained personnel increases with the level of education of the woman: from 42 percent among women with no education, it increases to 64 percent for those with primary education, and reaches 80 percent among women with a secondary education.

6.1.3 Place of Delivery

Among births occurring in the five years preceding the survey, 7 of 10 births (71 percent) took place in a health facility (Table 6.1). Attendance declined slightly at health facilities between 2010-2011 and 2012-2013, from 73 percent to 71 percent.

Examination of the data by background characteristics of the mother did not show a clear trend by maternal age. Differences were observed, however, by the area and region of residence. Delivery in health facilities was more prevalent among urban women (92 percent) than rural (60 percent); among those living in the West region (87 percent); and, to a lesser extent, in the Center (70 percent) and North (67 percent) regions than those living in the South, where only 54 percent of births took place in a health facility (Figure 6.2).

Figure 6.2 Health facility delivery by background characteristics

Similarly, the level of education of women seems to be a positive influence in the choice of delivery location. The higher the level of education, the higher was the proportion of women who gave birth in health facilities (65 percent among those with no education versus 93 percent for those with a secondary level of education).

6.2 CHILD HEALTH

6.2.1 Vaccination of Children

During the survey, information was recorded for all children born during the five years beforehand, enabling an assessment of the coverage of the Expanded Program on Immunization (EPI) in Senegal. A child is considered to be fully vaccinated when he or she has received the BCG vaccine (protection against tuberculosis); the measles vaccine; and three doses each of polio and DPT (diphtheria, tetanus, and pertussis) vaccines. Recently, a new combination, the pentavalent vaccine, has been used instead of DPT. Pentavalent actually contains five antigens against diphtheria, tetanus, and pertussis, as well as Hepatitis B and *Haemophilus influenzae* B (HIB). In addition, a first dose of vaccine against poliomyelitis (polio 0) is given at birth. According to the immunization schedule, these vaccines should be administered to the child before age 1. Data were also collected on yellow fever.

Immunization data were collected from two sources: the vaccination card of the child and statements from the mother (when the card was unavailable or did not exist). Table 6.2 presents the results of coverage by the various sources of information for children age 12-23 months, that is, those who, according to WHO recommendations, have reached the age at which they should have been fully vaccinated.

Table 6.2 Vaccinations by background characteristics

¹ Polio 0 is the polio vaccination given at birth.

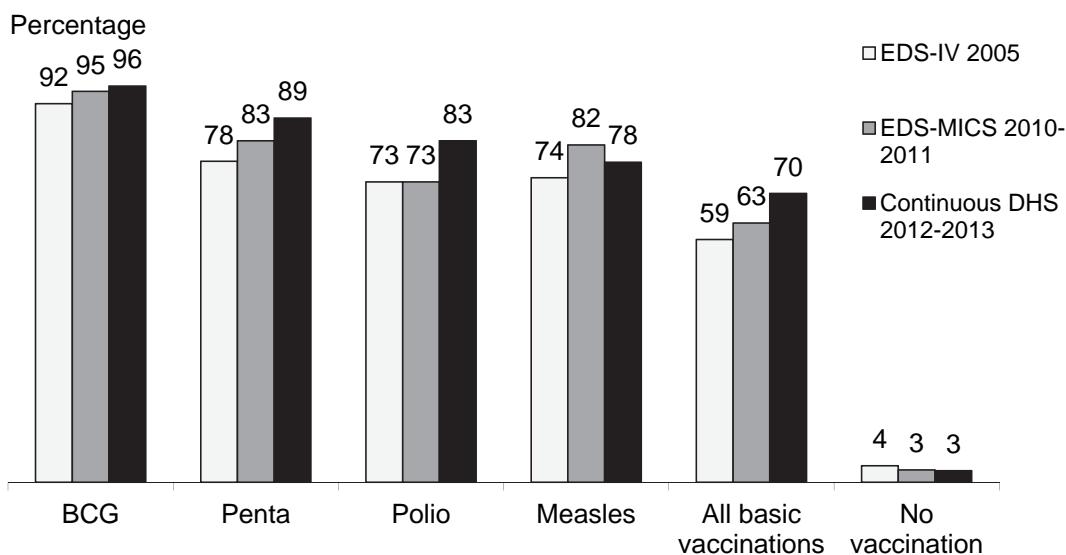

² BCG, measles, and three doses each of pentavalent and polio vaccine (excluding polio vaccine given at birth)

The results in Table 6.2 show that when all sources of information are combined, 7 children in 10 age 12-23 months (70 percent) have received all the EPI vaccines. The BCG vaccine was given (usually at birth) to 96 percent of children age 12-23 months. The proportion of children who received the first dose of the pentavalent vaccine is also very large (96 percent), but vaccine coverage decreases with the number of doses: from 96 percent for the first dose, it drops to 93 percent for the second dose, and falls to 89 percent by the third dose. The attrition rate² for this vaccine, quite low between the first and second doses (3 percent), increases between the second and third doses (5 percent); the overall attrition rate between the first and third doses is 8 percent.

Because the vaccine against polio is administered at the same time as the pentavalent vaccine, the coverage levels would be expected to be very similar. However, immunization coverage against poliomyelitis is slightly lower (polio 0: 72 percent, polio 1: 96 percent, polio 2: 92 percent, and polio 3: 83 percent) and shows greater attrition than the pentavalent between the first and third doses. Coverage against measles (78 percent) and yellow fever (77 percent) is the lowest of all vaccinations.

² The attrition rate for the pentavalent vaccine, for example, is the proportion of children who have been given the first dose of vaccine but who did not receive the third.

Figure 6.3 Vaccination of children age 12-23 months by the type of vaccine and three sources

Since the 2005 EDS-IV, coverage has improved for all vaccines except measles (Figure 6.3). The proportion of fully immunized children went up from 59 percent in 2005 to 63 percent in 2010-2011 and rose again to 70 percent in 2012-2013. On the other hand, coverage of measles has dropped slightly over the past two years, declining from 82 percent to 78 percent.

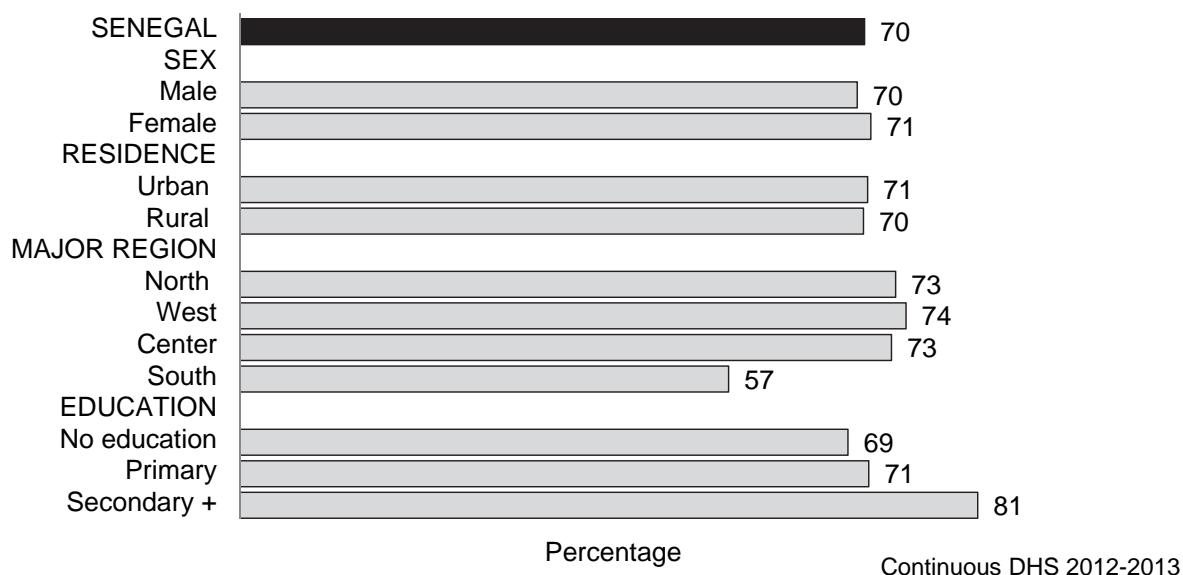

Table 6.2 and Figure 6.4 also present the immunization coverage of children age 12-23 months by select background characteristics of the mother and child. Virtually no difference in coverage is found by gender or place of residence (urban versus rural).

In contrast, the economic situation of the household reveals significant disparities, especially between children from households in the lowest wealth quintile and those in the highest wealth quintiles. The percentage of fully immunized children is 60 percent for the children in the lowest quintile, 76 percent for children from the middle and fourth quintiles, and 73 percent for the highest quintile.

The level of education of the mother is also a discerning variable for the vaccination of children: immunization coverage of children whose mothers have secondary or higher education is much higher (81 percent) than for children whose mothers have primary (71 percent) or no education (69 percent).

Among all children age 12-23 months, only 70 percent presented a vaccination card. Analysis by place of residence seems to indicate that the card was most often presented in urban areas (73 percent) versus 70 percent in rural areas.

Figure 6.4 Percentage of children age 12-23 months fully vaccinated, by background characteristics

6.2.2 Diseases of Children

Treatment of acute respiratory infections

Acute respiratory infections (ARIs), especially pneumonia, are one of the leading causes of child mortality in developing countries. To assess the prevalence of these infections among children, mothers were asked whether their children had suffered from cough during the two weeks preceding the survey, and if so, they were then asked if the cough was accompanied by short and rapid breathing, symptoms of acute respiratory infections (ARI). In addition, for children who had symptoms of ARI, the percentage of those whose mothers had sought treatment for them or advice from a health facility or health care provider was determined.

Among children under age 5, 3 percent had had a cough accompanied by short, rapid breathing in the two weeks preceding the survey (data not given). For these children, treatment or advice was sought from a health facility or health provider in 53 percent of cases (Table 6.3).

Given the low numbers of children with an ARI, it is difficult to analyze the results on the seeking of treatment by background characteristics. However, it should be noted that seeking treatment or advice from a health facility is slightly more frequent in boys than girls (55 percent compared with 52 percent). In addition, seeking treatment is also more common in urban areas (63 percent) than in rural areas (44 percent). Differences by major regions are particularly important: the West region (74 percent) have the most frequent use of a health facility for cases of ARI. On the other hand, treatment from a health provider or facility was least sought in the Center and South regions (43 percent and 45 percent, respectively). It also seems that seeking care is more common for children from households in the highest wealth quintiles than for children from the lowest wealth quintiles.

Table 6.3 Treatment of acute respiratory infection (ARI), fever, and diarrhea

Among children under age 5 who had symptoms of acute respiratory infection (ARI) or had fever in the two weeks preceding the survey, the percentage for whom advice or treatment was sought from a health facility or provider and the percentage who received antibiotics as treatment, according to background characteristics; among children under age five who had diarrhea in the two weeks preceding the survey, the percentage for whom advice or treatment was sought from a health facility or provider, the percentage given oral rehydration solution (ORS) and the percentage given oral rehydration therapy (ORT), by background characteristics, Continuous DHS, Senegal 2012-2013

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Symptoms of ARI (cough accompanied by short, rapid breathing which was chest-related and/or by difficult breathing which was chest-related) is considered a proxy for pneumonia.

² Excludes pharmacy, shop, and traditional practitioner

³ Includes oral rehydration salt packets and pre-packaged ORS fluid

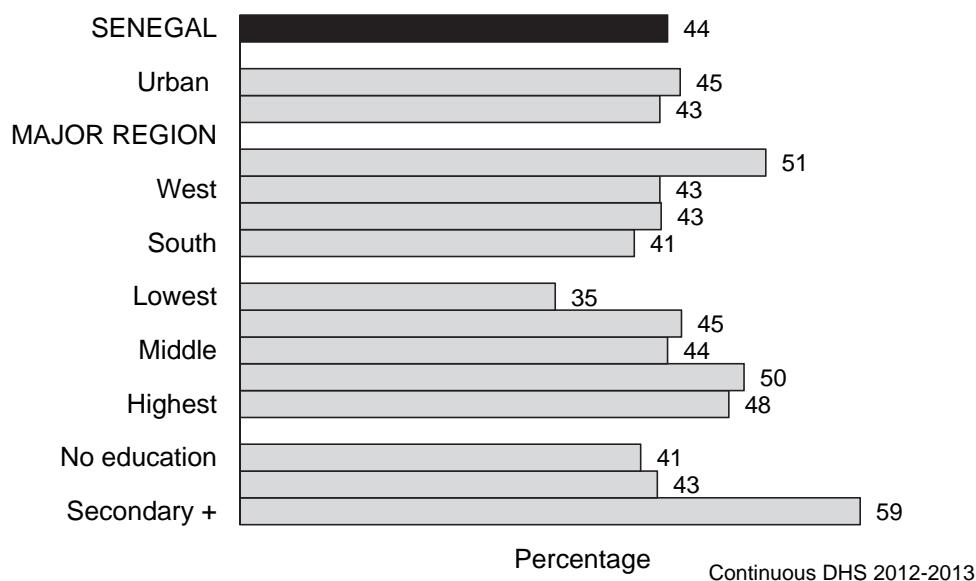

⁴ ORT includes fluid prepared from oral rehydration salt (ORS) packets, pre-packaged ORS fluid, and recommended home fluids.

Prevalence and early treatment of fever

Nearly 17 percent of children under age 5 had a fever in the last two weeks (data not shown). According to Table 6.3 treatment was sought at a health facility for 44 percent of children with a fever. Seeking treatment was more frequent in children under age 6 months (45 percent) and those age 12-35 months (46 percent) than for others. There were only slight differences by gender (44 percent for girls versus 43 percent for boys). Similarly, there was little disparity by area of residence: 45 percent in urban areas compared with 43 percent in rural areas (Figure 6.5). However, the use of health facilities is more common in the North region (51 percent) than in the three other regions (West: 43 percent, Center: 43 percent, and South: 41 percent). Mothers with secondary education or higher (59 percent) are characterized by a higher propensity for using health services in cases of fever in their children than their counterparts with primary level education (43 percent) and, especially, than those with no education (41 percent). According to the index of household

wealth, children from households in the two highest quintiles (50 percent and 48 percent) are clearly differentiated from children in households in the lowest quintile (35 percent).

Figure 6.5 Percentage of children under age 5 with fever for whom advice or treatment was sought from a health facility or provider

Prevalence and treatment of diarrhea

As a result of their consequences, including dehydration and malnutrition, diarrheal diseases are directly or indirectly a leading cause of death for young children in developing countries. To fight against the effects of dehydration, WHO recommends widespread use of ORT, either by use of a solution prepared from packets of oral rehydration salts or prepared at home with water, sugar, and salt.

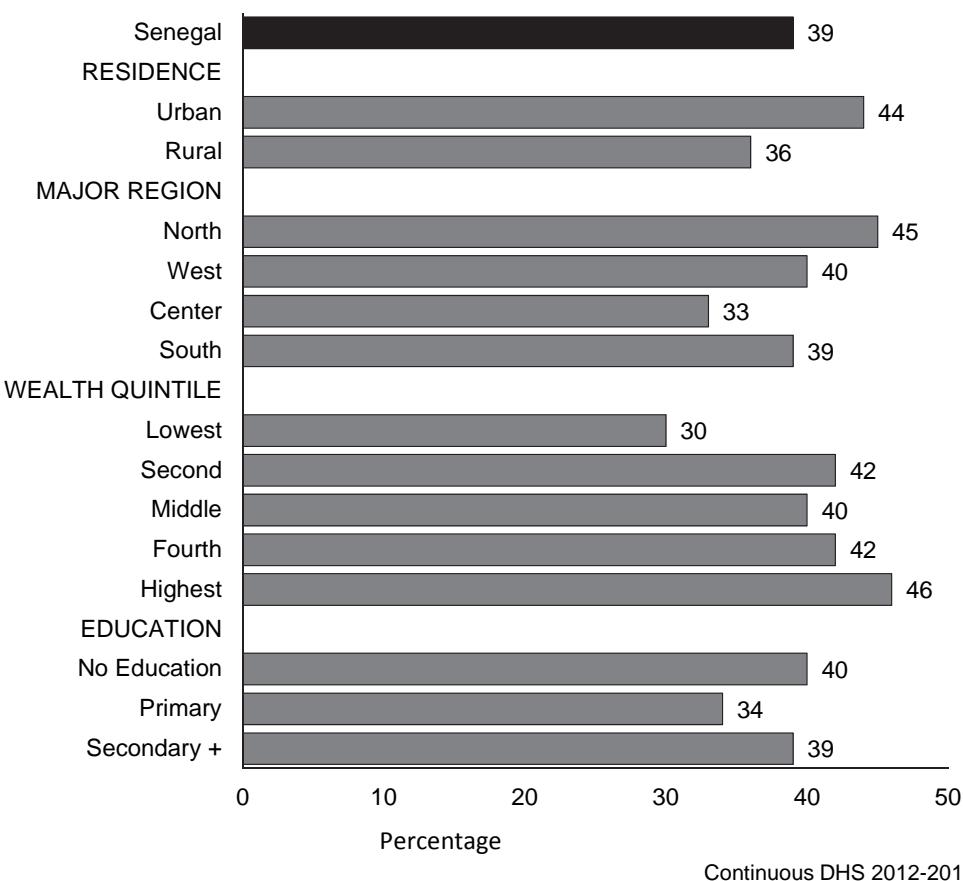

During the Continuous DHS, mothers were asked if their children had had diarrhea in the two weeks preceding the survey in order to measure the prevalence of diarrheal diseases in children under age 5. With regard to the treatment of diarrhea, mothers were asked if they had sought advice or treatment for their sick children, if they had been treated with ORS, and if they had used an ORT.

The prevalence of diarrhea among children under age 5 was 14 percent (data not shown). Table 6.3 and Figure 6.6 show that advice or treatment was sought at a health facility or health provider for only 39 percent of children with diarrhea during the two weeks preceding the survey.

Seeking care during episodes of diarrhea more often concerns children in urban areas (44 percent) than those in rural areas (36 percent). Treatment or advice was most frequently sought for those in the North region (45 percent). Children from households in the highest wealth quintile (46 percent) sought care more often than those in the lowest quintile.

No clear pattern appears for prevalence of diarrhea treatment according to level of education. Mothers with no education (40 percent) are as likely as those with the most education (39 percent) to seek treatment for their children with diarrhea.

Figure 6.6 Percentage of children under age 5 with diarrhea for whom advice or treatment was sought from a health facility or provider

To treat diarrhea in children, the use of ORS packets and pre-packaged ORS liquids or solutions prepared at home is recommended. Among children with diarrhea, 17 percent have been given a solution from ORT packets or pre-packaged ORS liquids. Overall, 22 percent received an ORT (ORS, pre-packaged ORS, or recommended home solutions).

It is among children age 12-23 months (20 percent) and 24-35 months (19 percent) that the use of ORS is the most common, although little difference by gender is seen. The difference is more significant between children in urban areas (20 percent) and those in rural areas (16 percent). Children from the Center region (20 percent) more frequently receive ORS than those in the rest of the country. However, no clear trend is seen according to the level of the mother's education. Children whose mothers have no education (19 percent) are more frequently given ORS than those whose mothers have primary level (11 percent) or those whose mothers have secondary education or more (17 percent).

ORS solution is supplemented with recommended home solutions more often for children age 48-59 months (35 percent) than at other ages. Girls (23 percent) are more frequently given an ORS with supplement than boys (20 percent). Children in urban areas (24 percent) are more frequently treated than those in rural areas (20 percent) with respect to ORS, as are those from the West (25 percent) and Center (23 percent) in comparison with those from other regions. Use of ORT is more frequent for children whose mothers have a secondary level of education or more (26 percent) or no education (23 percent) than for those whose mothers have primary school level education (14 percent). Finally, an increased use of ORT accompanies an increase in the level of household wealth.

NUTRITIONAL STATUS OF CHILDREN

Papa Ibrahima Sylmang SENE

Key Findings

- Breastfeeding is nearly universal in Senegal, and it is prolonged. Nearly 100 percent of children under age 6 months are breastfed, and at 12-15 months most children (97percent) continue to breastfeed.
- The recommendation for *exclusive* breastfeeding before age 6 months is not well respected; only about 40 percent of children under age 6 months are exclusively breastfed.
- In Senegal, 19 percent of children under age 5 have stunted growth, and for 6 percent stunting is severe.
- Approximately 9 percent of children are moderately or severely thin for their height, a sign of wasting.
- Among children age 6-59 months, 71 percent have anemia; 25 percent have a mild form, 42 percent a moderate form, and 4 percent a severe form. In 2011, 74 percent of children were anemic.

This chapter presents survey results about diet and nutritional status of children born in the five years preceding the survey. Breastfeeding practices and complementary feeding are topics addressed in the first part of the chapter. The second part is devoted to the results of anthropometric measurements (weight and height) from which nutritional status has been assessed. The last section covers the prevalence of anemia in children.

7.1 BREASTFEEDING AND COMPLEMENTARY FOODS

Feeding practices, in particular the use of breastfeeding, determine the nutritional status of children, which in turn affects their morbidity and mortality.

During the Continuous DHS, the interviewers asked mothers if they had breastfed their children born in the two years preceding the survey. More specifically, they asked how old the children were when they had initiated breastfeeding, how long they had breastfed, what was the frequency of breastfeeding, at what age complementary foods were introduced and what kind of foods they were, and finally how often various types of food were given to the child. Mothers were also asked if they had used a bottle.

The results in Table 7.1 show that at birth all children are breastfed and for some children this practice continues long after birth. At age 12-15 months, 97 percent of children are breastfed and at age 20-23 months, 47 percent are still being breastfed. However, while the World Health Organization (WHO) recommends that children be exclusively breastfed until age 6 months, exclusive breastfeeding is not the common practice (Figure 7.1). Indeed, at less than 2 months, only 57 percent of children are receiving only breast milk, and at 4-5 months, this proportion is only 18 percent. Overall, the proportion of children under age 6 months in exclusive breastfeeding is 38 percent, while 62 percent of children are receiving other liquids or solids in addition to breast milk, mainly water (46 percent). In contrast, between 6 and 9 months, an age when all

children should be receiving complementary foods in addition to breast milk, only two children in three are being fed in this way (65 percent).

Table 7.1 Breastfeeding status by age

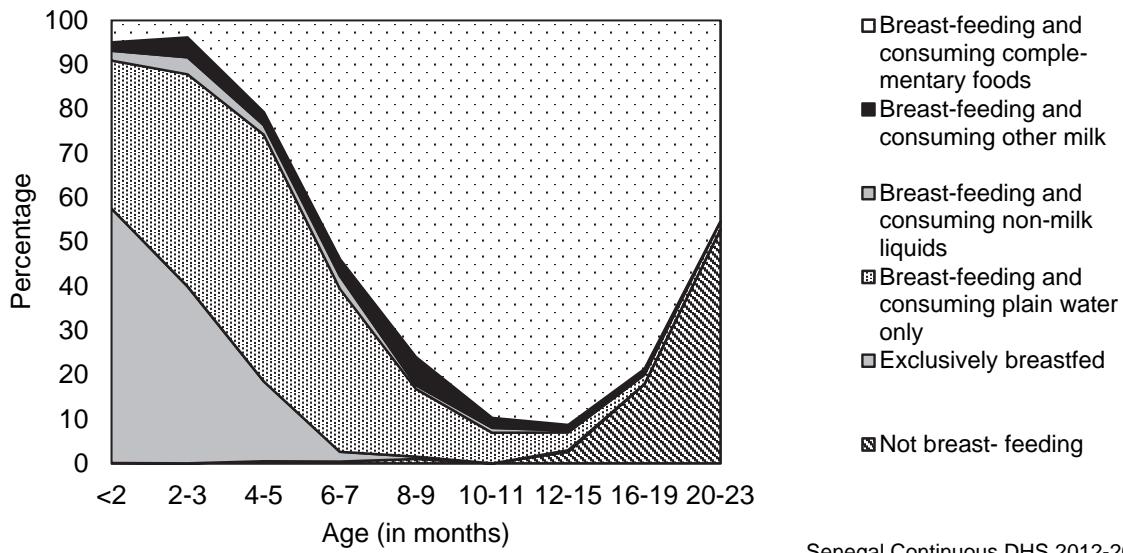

Percentage distribution of youngest children under age 2 living with their mother, by breastfeeding status; percentage currently breastfeeding; and percentage using a bottle with a nipple, according to age in months, Continuous DHS, Senegal 2012-2013

6-9	0.7	1.3	26.1	1.8	5.1	64.9	100.0	99.3	428	7.3	437

Note: Breastfeeding status refers to a 24-hour period (yesterday and last night). Children who are classified as breastfeeding and consuming plain water only consumed no liquid or solid supplements. The categories of not breastfeeding, exclusively breastfed, breastfeeding and consuming plain water, breastfeeding and consuming non-milk liquids, breastfeeding and consuming other milk, and breastfeeding and consuming complementary foods (solids and semi-solids) are hierarchical and mutually exclusive, and their percentages add up to 100 percent. Thus children who receive breast milk and non-milk liquids and who do not receive other milk and who do not receive complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary food are classified in that category as long as they are breastfeeding as well.

¹ Non-milk liquids include juice, juice drinks, clear broth, or other liquids.

Figure 7.1 Infant feeding practices by age

Senegal Continuous DHS 2012-2013

Exclusive breastfeeding of infants under 6 months is still low (38 percent). This practice is still growing. It was only 5 percent in 1992, 11 percent in 1997, 34 percent in 2005, and 39 percent in 2011.

Table 7.1 shows that the use of the bottle in children is somewhat rare because only 3 percent of those under age 2 months and 6 percent of those under age 6 months had received something in a bottle in the last 24 hours. However, this level has not changed compared with results from the EDS-MICS 2010-2011, where the percentage of children under age 6 months who took food from a bottle during the 24 hours preceding the survey was also 6 percent.

7.2 NUTRITIONAL STATUS OF CHILDREN

7.2.1 Methodology

Protein-energy malnutrition in children is a set of disorders characterized primarily by stunting, a stopping or delay in growth. It reflects both inadequate dietary intake and morbidity. Malnutrition can be evaluated by clinical criteria, biochemical analyses, or anthropometric measurements. However, for practical reasons, most nutrition surveys utilize anthropometric indicators. In children under age 5, the most commonly used indicators are weight based on age (weight-for-age), height depending on age (height-for-age) and weight depending on height (weight-for-height). These indices are expressed as standard deviation (Z-scores) relative to the median of WHO's international reference population (WHO, 2006).

The conventional definition of malnutrition in children, as given by WHO, is height-for-age, weight-for-height, or weight-for-age, that is lower by at least 2 standard deviations (Table 7.2). If the level reaches at least 3 standard deviations below the normal, then the malnutrition is considered severe:

- Height-for-age is a specific measure of stunting.
- Weight-for-height is a specific measure of thinness or wasting.
- Weight-for-age is a good reflection of the overall nutritional status of the child and can be used to monitor the weight gain of a child. However, it does not distinguish wasting from stunting.

Table 7.2 Significance of different measures of undernutrition

Prevalence (percentage) range used by WHO to categorize the public health significance of different measures of undernutrition (< -2 SD)

Indicators	Prevalence range in nutrition			
	Low	Medium	High	Very high
Height-for-age (stunted) (% of children Z < -2)	<20	≥20 et <30	≥30 et <40	≥40
Weight-for-age (underweight) (% of children Z < -2)	<10	≥10 et <20	≥20 et <30	≥30
Weight-for-height (wasted) (% of children Z < -2)	<5	≥ 5 et <10	≥10 et <15	≥15

7.2.2 Stunting

The results in Table 7.3 on the height-for-age index show that 19 percent of children in Senegal suffer from stunted growth; more than 1 in 20 (6 percent) have severe stunting. Stunting reflects chronic malnutrition. Overall, the nutritional status according to the height-for-age index can be characterized as acceptable, but this masks significant disparities by sociodemographic variables. First, the proportion of children with stunted growth is nearly twice as high in rural areas (21 percent) as in urban areas (13 percent).

According to age, there are significant differences in the prevalence of stunting, whether moderate or severe. The proportion of children with stunted growth increases with age. From 7 percent at less than 6 months, the prevalence of stunting increases to over 25 percent at 24-35 months before falling back to 18 between 48 and 59 months. Stunting affects boys slightly more often than girls (20 percent versus 17 percent).

With regard to the effect of birth interval, stunting affects 16 percent of children of first-time mothers. For multiparous women, the incidence of stunting in children decreases as the interval increases. Stunting is very significant when the interval is less than 24 months (29 percent) and decreases gradually to 16 percent for a birth interval greater than 48 months. The same trend is observed for severe stunting with a prevalence ranging from 3 percent to 10 percent.

When the mother does not live in the household, the table does not show any significant difference concerning the prevalence of stunting: 21 percent compared with 23 percent when the mother lives in the household and has not been interviewed and 18 percent when the mother lives in the household and has been interviewed.

The level of household wealth and the level of education of the mother are the variables for which the nutritional status of children shows the greatest variation. The prevalence of stunting in children declined steadily from 26 percent in households in the lowest wealth quintile to 11 percent in households in the highest wealth quintile. Children whose mothers have no education (21 percent) are more affected by stunting than those whose mothers have primary education (15 percent) and almost two times more affected than those with mothers who have secondary education or higher (10 percent). It is the same for severe stunting, which is 7 percent for children whose mothers have no education compared with 4 percent for children whose mothers have a primary level education and 2 percent for children whose mothers have secondary education or more (Figure 7.2).

Stunting is high among children age 24-35 months (25 percent), among children who were very small at birth (25 percent); for those whose mothers have no education (21 percent); and for those living in rural areas (21 percent), households in the lowest wealth quintile (26 percent), and in the Center (19 percent) and South (27 percent) regions.

Table 7.3 Nutritional status of children

Percentage of children under age 5 classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by background characteristics, Continuous DHS, Senegal 2012-2013

Note: Table is based on children who stayed in the household on the night before the interview. Each of the indices is expressed in standard deviation units (SDs) from the median of the WHO Child Growth Standards adopted in 2006. The indices in this table are NOT comparable to those based on the previously used 1977 NCHS/CDC/WHO Reference. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight.

¹ Recumbent length is measured for children under age 2 or in the few cases when the age of the child is unknown and the child is less than 85 cm; standing height is measured for all other children.

² Includes children who are below -3 standard deviations (SDs) from the WHO Growth Standards population median

² Includes children who are below -3 standard deviations (SDs) from the WHO Growth Standards population median

³ Excludes children whose mothers were not interviewed

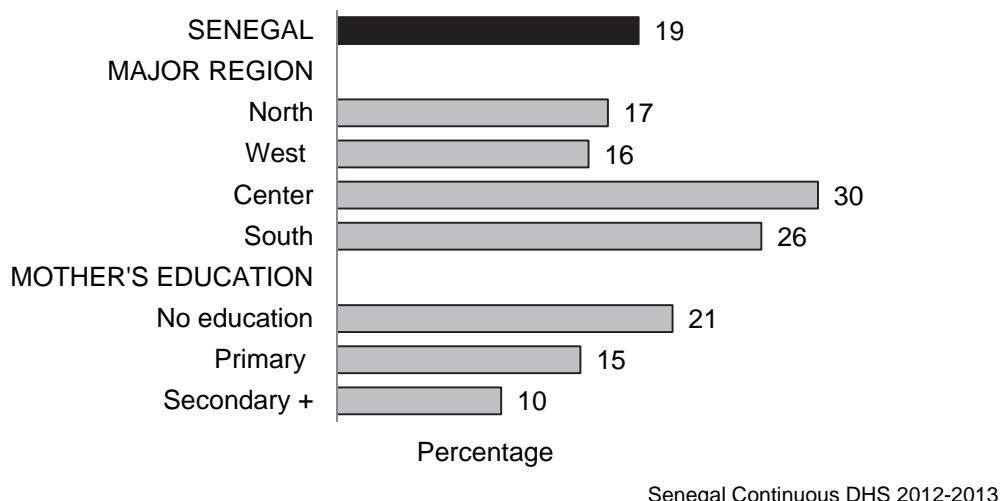

⁴ First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval.

⁵ Includes children whose mothers are deceased

⁶ For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire

⁷ Includes seven children whose weight at birth is missing and two children whose mother's education is missing

Figure 7.2 Prevalence of stunting (height-for-age)

7.2.3 Wasting or Thinness

Table 7.3 also shows the results for the proportions of children with thinness, measured by weight-for-height. Children whose weight-for-height falls below minus two standard deviations from the median of the reference population are considered to be thin or wasted, while those falling below minus three standard deviations are classified as suffering from a severe form of thinness (WHO and UNICEF 2009). Wasting reflects acute malnutrition.

Overall, acute malnutrition as a whole is high; nearly 1 child in 10 (9 percent) has a moderate or severe form of thinness; 2 percent are severely wasted. If age is considered, children under age 6-11 months are those who are most frequently wasted (13 percent). The prevalence declines between 12 and 35 months (7 percent) and increases once again for children age 36-47 months (9 percent) to 48-59 months (11 percent).

Acute malnutrition affects boys a little more often than girls (10 percent versus 8 percent). It is also higher in rural than urban areas (10 percent compared to 7 percent) and varies greatly depending on the region. It is much higher in the North (12 percent), South (11 percent), and Center (10 percent) regions than in the West (5 percent) region. The prevalence of wasting in children is also higher when the mother has no education (10 percent) than when she has a primary level (8 percent) and especially secondary (6 percent). The prevalence of wasting is related to the level of wealth in the household: as the level of wealth increases, the prevalence of wasting decreases (11 percent among children from households in the lowest quintiles compared to 6 percent for children in the highest quintiles).

7.2.4 Overweight and Obesity

Overweight is defined as a weight-for-height index higher than two standard deviations above the median. Overall, 1 percent of children under age 5 are overweight (Table 7.3). The prevalence of overweight is high in newborns under age 6 months (6 percent), but it drops very rapidly with age and is 2 percent for those age 10-11 months, 1 percent on average for children over 24-35 months, and finally less than 1 percent for children ages 36-47 and 48-59 months. Overweight is also more common in children whose mothers have a secondary level of education or higher (4 percent) than in children with less educated mothers (1 percent). No clear trend is evident by region or by level of household wealth.

7.2.5 Underweight

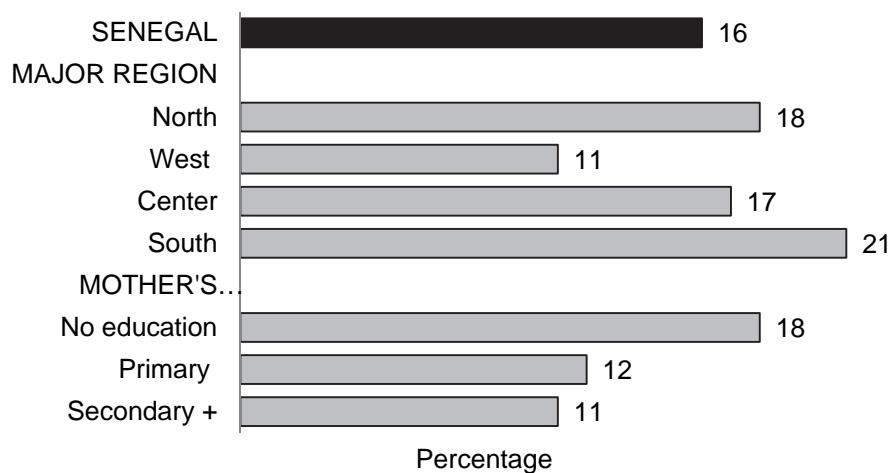

Table 7.3 also shows the nutritional status of children with a weight-for-age index. This is a combined index. Low weight-for-age can be caused by thinness just as it is caused by stunting. This index is the one most often used by health services to monitor nutritional progress and growth of children. Children whose weight-for-age is below minus two standard deviations from the median of the reference population are considered underweight, and those falling below minus three standard deviations are considered to be severely underweight. Underweight is a composite indicator that reflects both chronic and acute malnutrition at the same time. Nearly one in six children (16 percent) is underweight, and 3 percent are severely underweight. In 2011, 18 percent were underweight, and 5 percent were severely underweight.

Disparities in the prevalence of underweight according to sociodemographic characteristics are significant. Variations by age show that underweight is most common in children age 10-11 months (19 percent). This form of malnutrition occurs very early in life (affecting 6 percent at less than age 6 months), and increases rapidly, affecting 1 child in 10 (11 percent) by age 6-9 months.

Underweight is slightly more prevalent among boys (17 percent) than girls (14 percent). Children whose birth follows less than 24 months after an earlier birth are most likely to be underweight (21 percent), compared with 12 percent when the birth interval is higher than 48 months. Underweight is higher for children who are very small at birth (24 percent) versus 13 percent when the child is average or larger at birth. In rural areas, 18 percent of children are affected by this form of malnutrition compared with 11 percent in urban areas. The prevalence of underweight is higher in the South (21 percent), North (18 percent), and Center (17 percent) regions than in the West region (11 percent) (Figure 7.3).

Just as for stunting, the educational level of the mother is one of the most discriminating variables: 11 percent of children whose mothers have a secondary or higher education and 12 percent of those whose mothers have a primary education are underweight, compared with 18 percent of those whose mothers have had no education (Figure 7.3). Finally, the prevalence of underweight decreases with the level of household wealth; in the highest wealth quintile, 10 percent of children are underweight compared with 21 percent of children from households in the lowest quintile.

Figure 7.3 Prevalence of underweight (weight-for-age)

Senegal Continuous DHS 2012-2013

7.3 PREVALENCE OF ANEMIA IN CHILDREN

Table 7.4 shows that 7 in 10 children age 6-59 months are anemic: 25 percent with mild anemia, 42 percent with moderate anemia, and 4 percent with severe anemia.

Table 7.4 Prevalence of anemia in children

Percentage of children age 6-59 months classified as having anemia, by background characteristics, Senegal Continuous DHS 2012-2013

Fourth	69.1	28.4	38.7	2.1	906
Highest	61.7	26.6	33.8	1.4	871
Total ³	71.2	25.3	41.9	4.0	5,293

Note: Table is based on children who stayed in the household on the night before the interview and who were tested for anemia. Prevalence of anemia, based on hemoglobin levels, is adjusted for altitude using formulas from CDC, 1998. Hemoglobin in grams per deciliter (g/dl).

¹ Includes children whose mothers are deceased

² For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

³ Includes two children whose mother's education is missing

Anemia peaks in children at age 12-23 months. The prevalence increases from 78 percent at 6-9 months to 83 percent at 12-23 months and then decreases to 54 percent by 48-59 months. The results show differences between the sexes (74 percent of boys and 69 of girls are anemic), between areas of residence (65 percent of urban and 75 percent of rural children are affected), and by region (66 percent in the North, 69 percent in the West, 71 percent in the South, and 77 percent in the Center have anemia). When the mother has no education, the proportion of anemic children is 74 percent versus 67 percent when she has primary level education and 62 percent when she has at least a secondary level of education.

The majority of children with anemia are moderately anemic (59 percent). Children with severe anemia have a different sociodemographic profile from those with mild anemia. The prevalence of severe anemia in the most affected regions (Center and South) is thus two to four times higher than in the less affected areas (the West and North regions). Similarly, children of mothers with no education suffer nearly two times more frequently from severe anemia than those whose mothers have a primary level (5 percent versus 3 percent) and nearly four times more frequently than those with mothers who have had secondary schooling (1 percent).

The prevalence of anemia has dropped slightly since the EDS-MICS 2010-2011, from 76 percent to 71 percent. This slight decrease relates to severe anemia (now 4 percent versus 5 percent) and moderate anemia (now 42 percent versus 48 percent). Mild anemia has increased slightly (from 23 percent to 25 percent).

Mohamed AYAD, Salif NDIAYE, Moussa DIAKHATÉ, and Magatte NDIAYE¹

Key Findings

- More than 76 percent of households have at least one mosquito net, and 73 percent of households have at least one insecticide-treated net, which is generally a long-lasting insecticidal net (68 percent).
- In all, 41 percent of household members slept under an insecticide-treated net the night before the survey, and in households with at least one such net, this proportion rose to 51 percent. For children under age 5, these proportions are, respectively, 46 percent and 55 percent; for pregnant women, they are, respectively, 43 percent and 51 percent.
- Approximately 9 of 10 pregnant women (88 percent) have taken preventive antimalarial drugs during their last pregnancy, but only 41 percent received at least two doses of SP/Fansidar, with at least one of them given during an antenatal visit, as recommended in the context of intermittent preventive treatment.
- Among the 17 percent of children under age 5 who had a fever during the two weeks preceding the survey, 6.2 percent were treated with antimalarials, including 1.3 percent treated with artemisinin-based combination therapy (ACT).
- Only 2.8 percent of children age 6-59 months have tested positive for malaria through a microscopic diagnosis (thick blood smear).

Malaria is caused by a parasite, *Plasmodium*, which is transmitted by mosquitoes.. The populations that are most vulnerable to malaria are children under 5 and pregnant women. In Africa the burden of malaria remains greater than in other parts of the world. In its 2010 report on malaria worldwide, WHO has shown that in 11 African countries the number of confirmed malaria cases, hospitalizations, and deaths from the disease has dropped by more than 50 percent over the past decade. These positive results are the consequence of a sustained effort to eliminate deaths from malaria by 2015. Important advances have been made through the mass distribution of insecticide-treated nets (ITNs), development of programs for indoor spraying of residual insecticide, diagnosis using rapid diagnostic tests (RDTs), and greater use of artemisinin-based combination therapy (ACT).

In Senegal, the National Program against Malaria [Programme National de Lutte contre le Paludisme] (PNLP) has included in its strategic planning the promotion of the use of insecticide-treated nets (ITNs) as a focus of a major intervention to reduce morbidity and mortality related to malaria. This choice is in line with the recommendations made by WHO and is justified by an 18 percent reduction of infant mortality between 2000 and 2010 (Roll Back Malaria, 2010). Thus, the PNLP set a goal of achieving an ITN usage rate of 80

¹ The authors would like to thank the PMI team from Dakar, Senegal, for their agreement to read the chapter on malaria and for their pertinent observations.

percent in 2010. To achieve this objective, the PNLP and its partners implemented programs for the supply and distribution of long-lasting insecticidal nets (LLINs). This distribution is made during routine activities of health facilities and community organizations (subsidized sales) and also through free distribution campaigns.

Senegal also adopted a policy for the therapeutic treatment of malaria in 2003. This therapy consists of prescribing Artemisinin-based Combination Therapy (ACT) in health facilities. To treat uncomplicated malaria, new ACT treatment protocols are being adopted by health providers in all health facilities, including those at the community level. During the period before the arrival of the first ACTs, the policy prescribed the combination of sulfadoxine-pyrimethamine (SP) and amodiaquine. Beginning in the first half of 2006 with the arrival of artesunate–amodiaquine, the new protocols were implemented. As for quinine, it is only indicated for severe cases of malaria in children, adults, and pregnant women.

Rapid diagnostic tests (RDTs), the subject of a feasibility and acceptability study at the operational level in 2006, have proven indispensable for proper management of cases and for better understanding malarial morbidity in the country. Therefore, in the third quarter of 2007, the PNLP proceeded to implement this diagnostic tool in health facilities by first training providers and then freely allocating RDTs. The implementation of RDTs was accompanied by the introduction of a flow chart for the diagnosis and management of uncomplicated malaria. This flowchart requires RDTs for people of any age with a fever who do not show signs suggestive of other febrile illnesses, and only cases that test positive are treated.

The information collected in the first year of the Continuous DHS 2012-2013 in Senegal assesses the interventions that have been conducted in the campaign against malaria in order to highlight the progress and efforts needed to strengthen prevention in Senegal.

8.1 MOSQUITO NETS AND INDOOR SPRAYING

Malaria is prevented by taking precautions to reduce the risk of infections and by using certain medications. Use of ITNs and indoor residual spraying (IRS) of insecticide are among the most effective means of prevention.

The strategic option chosen by the PNLP is one of universal access to LLINs to ensure better coverage and more use of LLINs, particularly by the most vulnerable populations. Indoor residual spraying is also a key component of the strategy in the campaign against malaria.

8.1.1 Possession of Mosquito Nets

The data collected during the Continuous DHS 2012-2013 were used to assess the proportions of households with mosquito nets, treated or untreated; those with ITNs; and those with an LLIN. An LLIN is a mosquito net impregnated with insecticide by the manufacturer. An ITN is either an LLIN or a pre-treated mosquito net obtained fewer than 12 months ago or a mosquito net soaked in insecticide fewer than 12 months ago.

Table 8.1 shows the percentage of households with at least one mosquito net of any type, those with more than one net, and the average number of nets per household. The same information is provided for possession of ITNs and LLINs.

Table 8.1 Household possession of mosquito nets

Percentage of households with at least one mosquito net (treated or untreated), insecticide-treated net (ITN), and long-lasting insecticidal net (LLIN); percentage of households with more than one net, ITN, and LLIN; and average number of nets, ITNs, and LLINs per household, by background characteristics, Continuous DHS, Senegal 2012-2013

Background characteristic	Any mosquito net			Insecticide-treated mosquito net (ITN) ¹			Long-lasting insecticidal net (LLIN)			Number of households
	Percentage having at least one per household	Percentage having more than one per household	Average number of nets per household	Percentage having at least one per household	Percentage having more than one per household	Average number of ITNs per household	Percentage having at least one per household	Percentage having more than one per household	Average number of LLINs per household

Total	75.9	63.6	3.0	72.8	60.2	2.8	67.5	55.1	2.5	4,175

¹ An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.

More than three of four households (76 percent currently versus 72 percent in the EDS-MICS 2010-2011) have at least one mosquito net. Most nets are treated: 73 percent of households have an ITN type of mosquito net, and 68 percent have an LLIN. In the EDS-MICS 2010-2011, these proportions were, 60 percent and 58 percent, respectively.

The proportion of households with at least one type of insecticide-treated net is higher in rural areas (89 percent) than in urban areas (56 percent). Depending on the time of collection, possession of mosquito nets did not differ between the first round (*field work between September and January, which corresponds for the most part to the rainy season*) and the second round (*field work between February and June, which corresponds for the most part to the dry season*). In contrast, the variations across major regions are considerable; the lowest proportions are found in the West (regions of Dakar and Thiès: 50 percent). More nets are found in the South (regions of Tambacounda, Ziguinchor, Sédiou, Kolda, and Kédougou: 86 percent) and the Center (regions of Kaolack, Diourbel, Fatick, and Kaffrine: 88 percent). The highest proportion is observed in the North (regions of Matam, Louga, and Saint Louis: 93 percent). Similar variations are observed for treated nets of the LLIN type. In the transition zones, Zone II, which corresponds to the major Center region (Doorbell, Kaolack, Fatick and Kaffrine) and Zone III, which corresponds to the greater South region (Ziguinchor, Tambacounda, Kolda, Kédougou and Sédiou), have very similar proportions of households with at least one ITN: 88 percent and 86 percent, respectively. In Zone I, which corresponds to the two major regions of the North and the West (Dakar, Saint Louis, Thiès, Louga, and Matam), the proportion (63 percent) is significantly lower than in the other two zones. Note that the regions of Dakar and Thiès had not yet been

covered by the PNLP program strategy of universal coverage for more than half of the collection period. Moreover, the regions that had received universal coverage before data collection all had LLIN ownership rates of over 80 percent.

An average household has three mosquito nets of any type (versus 2.3 nets in the EDS-MICS 2010-2011). Ownership of ITNs averages 2.8 per household. In households with more than one LLIN, the average number is 2.5 per household.

Notable differences are found according to wealth quintile. Possession of mosquito nets decreases with improvement in the economic level of households. Households in the highest quintiles are less exposed to mosquitoes or can get other means of protection, such as insecticides to spray or screens or curtains to place in the doors and windows.

8.1.2 Indoor Residual Spraying

IRS is a vector control technique that consists of spraying liquid insecticide on the interior walls of residential dwellings. Its effect is twofold:

- Lethal: Anopheles mosquitoes inside the house die within a few moments of landing on the walls.
- Repellent: Anopheles mosquitoes outside the house are deterred from entry.

In addition, some insecticides used in IRS greatly reduce the presence of other pests such as cockroaches and flies.

In Senegal, IRS is a main focal point of strategic intervention in the campaign against malaria waged by the PNLP. However, given its cost and complexity, IRS has only been implemented in a few health districts in the regions of Saint Louis, Tambacounda, Kaolack, Kédougou, and Kolda. Overall, the results in Table 8.2 show that 12 percent of the households surveyed reported that the internal walls of their homes were sprayed in the 12 months preceding the survey. This percentage was 9 percent in the EDS-MICS 2010-2011.

Differential analysis of IRS according to select background characteristics of households shows that residential dwellings in rural areas are sprayed more frequently than those in urban areas (15 percent versus 9 percent). Depending on the time of collection, the spraying is more common during the second round than in the first round (14 percent versus 10 percent). By major region, the Center and South regions are at the top with 20 percent. In the West and North regions, the proportions are only 6 percent and 4 percent, respectively. According to the epidemiological profile for malaria, the proportions are 20 percent each in Zones II and III and only 6 percent in Zone 1. The percentage of households sprayed also varies by wealth quintile (20 percent in the lowest quintile and less than 8 percent in the highest quintile).

Table 8.2 Indoor residual spraying against mosquitoes by background characteristics

Percentage of households in which someone has come into the dwelling to spray the interior walls against mosquitoes (IRS) in the past 12 months, the percentage of households with at least one ITN and/or IRS in the past 12 months, by background characteristics, Continuous DHS, Senegal 2012-2013

Highest	7.8	48.5	1,042
Total	11.6	75.5	4,175

¹ Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or non-governmental organization.

² An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.

The same table shows that a majority of Senegalese households (76 percent) have at least one ITN and/or have had IRS in the last 12 months. Overall, differential analysis of this indicator according to household characteristics shows results that are similar to those related to the possession of mosquito nets reported in Table 8.1.

8.1.3 Use of Mosquito Nets by Persons in the Household

The PNLP has set a goal of 80 percent for ITN use in the general population. Special attention is always given to vulnerable groups such as children under age 5 and pregnant women. To assess the level of net use by the population during the survey, respondents were asked for a list of all persons who had slept under each mosquito net the night preceding the interview. Information on each person's age and the pregnancy status of women provided the frequency of net use in the general population (all ages and all sexes combined), as well as net use among the two vulnerable groups of children under age 5 and pregnant women.

Table 8.3 on the use of mosquito nets by the general population shows that 43 percent of members in the households interviewed had slept under a net of any type the night preceding the survey (in the EDS-MICS of 2010-2011, the proportion was 35 percent). This level of use remains relatively low compared with the target goal of 80 percent set for this indicator. Approximately 41 percent of household members reported that they had slept under an ITN-type net and 37 percent under an LLIN type (these proportions were respectively 29 percent and 25 percent in the EDS-MICS of 2010-2011). In addition, 49 percent of household members slept under an ITN net the night before the survey or in a dwelling whose interior walls had been sprayed in the last 12 months. Finally, among households with ITNs, 51 percent of members slept under this type of mosquito net the previous night. The results of this survey clearly indicate a significant improvement in the use of nets compared with results of the EDS-MICS 2010-2011.

Among household members, children under age 5 and adults age 50 or older make up the groups that most often slept under a mosquito net (discussed later for children under age 5). In addition, female members of households (43 percent) and those in rural areas (45 percent) are relatively more likely to have slept under an ITN than male household members (39 percent) or those living in urban areas (35 percent).

Interregional differences are quite significant. The North has a large proportion of the population (61 percent) that sleeps under an ITN-type mosquito net. In the other three major regions, usage is 48 percent in the Center, 40 percent in the South, and only 24 percent in the West. Moreover, the percentage who slept under an ITN the night before the survey or in housing sprayed for mosquitoes over the last 12 months is higher in the Center and North regions (63 percent) than in the South (56 percent) and West (29 percent). According to transmission zones, the level of coverage of household members who slept under an ITN is highest in Zone II (48 percent), followed by Zone III (40 percent). In Zone I, the percentage is only 37 percent. The use of ITNs during the first round of data collection is much higher (46 percent) than during the second round (36 percent).

Regarding the wealth quintile, the highest proportion of household members with at least one ITN who slept under a mosquito net is found in the middle quintile (54 percent) and the lowest proportion is found among those in the highest quintile (28 percent).

Table 8.3 Use of mosquito nets by persons in the household

Percentage of the de facto household population who slept the night before the survey under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), under a long-lasting insecticidal net (LLIN), and under an ITN or in a dwelling in which the interior walls have been sprayed against mosquitoes (IRS) in the past 12 months; and among the de facto household population in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Continuous DHS, Senegal 2012-2013

¹ An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.

² Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or non-governmental organization.

³ Includes 11 household members whose age is missing.

8.1.4 Use of Mosquito Nets by Vulnerable Groups

Although the Ministry of Health and Social Action has set a goal to protect the general population with ITNs, it nevertheless gives special attention to pregnant women and children under age 5. These two vulnerable population groups are the subject of special monitoring.

Use of mosquito nets by children under age 5. Table 8.4 shows the proportion of children under the age 5 who slept under a mosquito net the night preceding the survey, for each type of net and by select background characteristics.

Table 8.4 Use of mosquito nets by children

Percentage of children under age 5 who, the night before the survey, slept under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), under a long-lasting insecticidal net (LLIN), and under an ITN or in a dwelling in which the interior walls have been sprayed against mosquitoes (IRS) in the past 12 months; and among children under age 5 in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Continuous DHS, Senegal 2012-2013

Background characteristic	Children under age 5 in all households				Children under age 5 in households with at least one ITN ¹

Highest	34.6	33.8	29.4	38.0	1,033	55.6	627
Total	48.0	45.8	42.2	54.4	6,340	55.0	5,279

Note: Table is based on children who stayed in the household the night before the interview.

¹ An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.

² Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or non-governmental organization.

It is clear from this table that nearly one in two children (48 percent) slept under some kind of mosquito net the night preceding the survey. In the EDS-MICS 2010-2011, this proportion was only 41 percent, so there has been an increase of 17 percent. Approximately 46 percent of children slept under an ITN and 42 percent under an LLIN type net (these proportions were respectively 35 percent and 31 percent in the EDS-MICS 2010-2011). In addition, more than 54 percent of children slept under an ITN or in a house where the interior walls had been sprayed in the last 12 months. Finally, among children living in households with at least one ITN net, 55 percent slept under this type of mosquito net the night before the survey.

The proportion of children who slept under an ITN does not vary significantly with the age of the child: it is 48 percent among children age 24-35 months and 44 percent for those age 36-47 months. Gender differences are also not large (47 percent among boys compared with 45 percent for girls). Use of an ITN mosquito net is slightly more common in rural areas (47 percent) than urban areas (44 percent).

There is a significant variation depending on the time of collection; indeed, the level of ITN use among children under age 5 is higher during the first round (50 percent) than during the second round (42 percent). By region of residence, there is also a significant difference in the level of ITN net use; the West (30 percent) and South (44 percent) have the lowest proportions. Conversely, the North (64 percent) and Center (51 percent) have the highest levels of use. According to the epidemiological profile for malaria, the level of ITN net use is higher in Zone II (51 percent) than in the other two zones (44 percent each).

As in the general population, children under age 5 living in households with the highest wealth quintile have the lowest levels of mosquito net use.

Use of mosquito nets by pregnant women. Table 8.5 presents by type of net the percentages of pregnant women age 15-49 who slept under a mosquito net the night preceding the survey. More than two of five pregnant women (45 percent) slept under a net of any type; with regard to ITNs, the proportion is 43 percent and for LLINs, the proportion is 40 percent. In the EDS-MICS of 2010-2011, these percentages were 42 percent, 36 percent, and 32 percent, respectively. In addition, one in two pregnant women (50 percent) slept under an ITN mosquito net or in housing where the interior walls had been sprayed in the last 12 months. Among pregnant women living in a house with at least one ITN mosquito net, 51 percent slept under this type of mosquito net the night preceding the survey.

The percentages of pregnant women who used a mosquito net are higher in rural areas than in urban areas. For ITNs the proportions are 47 percent in rural areas versus 36 percent urban areas and, for LLINs, 43 percent rural versus 34 percent urban. Pregnant women use ITNs much more often during the first round (49 percent) than in the second round (38 percent) of data collection. Usage also varies according to major region. The North (64 percent) has the highest proportion of use followed by the Center (47 percent) and the South (46 percent). In the West, the level of 24 percent is much lower. According to the epidemiological profile for malaria, differences in the level of ITN use are not pronounced: Zone II (47 percent), Zone III (46 percent), and Zone I (40 percent) are similar percentages. Differences are noted, however, in the use of ITNs according to level of education. The percentage of pregnant women users increases in relation to the level of education. It is also notable that the percentage of pregnant women using ITNs is greatest in households from the middle quintile (58 percent compared with a minimum of 36 percent in the fourth quintile).

Table 8.5 Use of mosquito nets by pregnant women

Percentages of pregnant women age 15-49 who, the night before the survey, slept under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), under a long-lasting insecticidal net (LLIN), and under an ITN or in a dwelling in which the interior walls have been sprayed against mosquitoes (IRS) in the past 12 months; and among pregnant women age 15-49 in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Continuous DHS, Senegal 2012-2013

Note: Table is based on children who stayed in the household the night before the interview.

¹ An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.

² Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or non-governmental organization.

Finally, significant progress can be noted in the use of mosquito nets by pregnant women between 2010-2011 and 2012-2013. The percentage of use increased from 42 percent to 45 percent for both treated and untreated mosquito nets (a relative increase of 9 percent), from 36 percent to 43 percent for ITNs (a relative increase of 20 percent), and from 32 percent to 40 percent for LLINs (a relative increase of 25 percent).

8.2 PREVENTIVE TREATMENT OF MALARIA DURING PREGNANCY

During the Continuous DHS 2012-2013, women who had given birth in the last two years were asked whether they had taken preventive antimalarial drugs during their last pregnancy and, if so, what type of drugs they had taken. Table 8.6 shows that 88 percent of pregnant women have taken antimalarial drugs as a preventive measure during their last pregnancy in the two years preceding the survey (in the EDS-MICS 2010-2011, this proportion was 85 percent). In accordance with the policy guidelines for intermittent preventive treatment (IPTp), 76 percent of women received SP (*sulfadoxine-pyrimethamine*) during their last pregnancy, nearly 74 percent received IPTp of SP during a routine antenatal visit, 42 percent took two doses or more, and more than 41 percent received the two or more recommended doses, at least one of them during an antenatal visit. In the EDS-MICS 2010-2011, these percentages were 68 percent, 65 percent, 42 percent, and 39 percent, respectively.

Table 8.6 Use of antimalarial drugs for prevention of malaria and use of intermittent preventive treatment (IPTp)¹ by women during pregnancy

Percentage of women age 15-49 with a live birth in the two years preceding the survey who, during the pregnancy preceding the last birth, received any antimalarial drug for prevention of malaria, received any SP during an ANC visit, and who took at least two doses of SP and received at least one dose during an ANC visit, by background characteristics, Continuous DHS, Senegal 2012-2013

¹ IPTp: Intermittent preventive treatment (IPTp) during pregnancy is a preventive treatment of two doses or more of SP.

Regional differences are very significant. The percentage of women who took two or more of the recommended doses of IPTp during the last pregnancy is 56 percent in the West, followed by 41 percent in the Center. In the North and South, the percentage does not exceed 33 percent. Differences between cities and the countryside are also pronounced (53 percent in urban areas versus 37 percent in rural areas). The percentage of women who had two or more doses of IPTp is, in addition, higher among women with primary school (51 percent) or secondary education and higher (45 percent) than for those who have never been to school (39 percent). This percentage is also higher among women belonging to households in the three highest wealth quintiles than for those who are part of the two lowest quintiles.

The differences between the IPTp 1 (SP during a routine antenatal visit) and the IPTp 2 (two or more doses of SP during a routine antenatal visit) remain very significant at the national level (31 percentage points higher for two doses of SP). It is among women from rural areas (32 percentage points), those from the Center region (38 percentage points), those living in Zone II (38 percentage points), and those in the second round (33 percentage points) where the greatest differences are found between the IPTp 1 and IPTp 2.

In relation to level of education, it is among women with no education where the greatest percentage gap is found (33 percentage points). With regard to wealth quintiles, the greatest gap among women is among those belonging to the second and third quintiles (33 percentage points).

8.3 FEVER AND ANTIMALARIAL TREATMENT OF CHILDREN UNDER AGE 5

The survey also asked whether children under age 5 had had a fever during the two weeks preceding the survey. If the answer was positive, a series of questions about the treatment of fever were then asked (see Chapter 6 on Child Health). These questions focused on the taking of antimalarial drugs and when antimalarial treatment was administered for the first time. The results are presented in Table 8.7.

The results show that 17 percent of children under age 5 had a fever in the two weeks preceding the survey. This proportion is significantly lower than that recorded in the EDS-MICS of 2010-2011, which was 23 percent.

The greatest variations in the prevalence of fever are related to the child's age and region of residence and also the collection period. Indeed, the proportion of children who had a fever generally decreased with age, dropping from a maximum of 22 percent among those younger than 12-23 months to a minimum of 10 percent for children age 48-59 months.

Results by area of residence show a higher prevalence in urban areas (18 percent) than in rural areas (16 percent) and in the first round (19 percent) than in the second round (14 percent). At the regional level, the South (26 percent) is the most affected area, while at the opposite end of the spectrum, the North (12 percent) is the least affected region. In addition, the results show that the proportion of children who had a fever was slightly higher among those living in households in the highest wealth quintile (19 percent) than among those in the lowest wealth quintile (18 percent).

Among children who had a fever, 6 percent were treated with antimalarial drugs. In addition, in 3 percent of cases, the antimalarial were started early, that is, the same day the fever appeared, or the next day.

Table 8.7 Prevalence and prompt treatment of children with fever

Percentage of children under age 5 with fever in the two weeks preceding the survey; among children with fever, the percentage who took antimalarial drugs, and the percentage who took the drugs the same or next day following the onset of fever, by background characteristics, Continuous DHS, Senegal 2012-2012

Wealth quintile					
Lowest	17.5	1,453	6.8	2.4	254
Second	15.6	1,323	3.4	0.2	206
Middle	14.6	1,225	2.0	1.6	179
Fourth	17.1	1,066	8.5	4.1	182
Highest	18.7	1,010	10.2	5.9	189
Total	16.6	6,078	6.2	2.8	1,010

The following variations were observed with regard to treatment of fever with antimalarial drugs according to select background characteristics:

- The highest proportion of children with fever who are treated is children age 24-35 months (12 percent) and those age 48-59 months (8 percent).
- Children who were treated are proportionally more likely to be treated during the first round (8 percent) than in the second round (3 percent).
- The proportion of children with fever who were treated with antimalarial drugs varies from 5 percent in rural areas to 8 percent in urban areas.
- The proportion of children treated with antimalarial drugs is higher among those whose mothers have at least secondary education or more (15 percent) than among those whose mothers have a primary level education (6 percent) or no education (5 percent).
- Treatment is also more common among children living in households in the two highest wealth quintiles (respectively 9 percent and 10 percent) than those in a household belonging to the three other quintiles (varying from 2 percent to 7 percent).
- Children from the two major regions of the West (9 percent) and the South (7 percent) more often received antimalarials than children from the North or Center regions.

The proportion of children treated early with antimalarials is lower than the percentage treated at any time (3 percent versus 6 percent). There are probably several reasons why mothers are not able to treat fever promptly (availability of antimalarials, distance, cost, or the belief that the fever is not malarial in origin). For children under 5 who had a fever, Table 8.8 shows the proportion of those who took different types of antimalarials and the proportion of those who took them early, right after the onset of fever.

Note that 1.3 percent (versus 0.7 percent in the EDS-MICS of 2010-2011) of children with fever were treated with amodiaquine, and 0.9 percent (versus 1.4 percent in 2010-2011) received treatment on the same day or the day following the onset of fever. The percentage of ACTs used is low; 1.3 percent of children received them at some time and 0.5 percent received them early. Other medication categories are, in order of use, the category other antimalarials (3.5 percent) and quinine (0.5 percent). Finally, the proportion of children treated with SP is negligible (0.3 percent).

Results on the use of ACTs against malaria according to major region show proportions of children treated are highest in the South and Center (2.5 percent and 1.5 percent, respectively). In the North, the use of ACTs is virtually non-existent. According to the epidemiological profile for malaria, the use of ACTs is more common in Zone III (2.5 percent) followed by Zone II. The use of ACTs in Zone I is extremely low (0.4 percent). Changes according to place of residence and sex are not significant. In terms of the collection period, children are treated much more often with ACTs during the first round (2.0 percent) than during the second round (0.3 percent).

Table 8.8 Type of antimalarial drugs used

ACT = artemisinin-based combination therapy.

8.4 HEMOGLOBIN RATES

In countries where malaria is endemic, a hemoglobin level less than 8.0 g/dl is considered to be an indirect indicator of the prevalence of anemia due to malaria. At the national level, 10 percent of children age 6–59 months have a hemoglobin rate less than 8.0 g/dl (Table 8.9). The prevalence was 14 percent in the EDS-MICS of 2010-2011; thus a decrease of 28 percent has occurred between the two surveys.

Table 8.9 Hemoglobin <8.0 g/dl in children

Note: Table is based on children who stayed in the household the night before the interview.

¹ Includes children whose mothers are deceased

² For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire

Variations exist depending on certain characteristics:

- The proportion of children with a hemoglobin level below 8.0 g/dl is highest among children age 12-23 months (17 percent).
- It is slightly higher in boys (11 percent) than in girls (9 percent).
- It is significantly higher among rural children than among urban (13 percent versus 6 percent).

- The highest proportion is observed in the two major regions of the Center and South (14 percent). In the other two major regions, the prevalence is lower than the national average (8 percent in the West and 5 percent in the North).
- When the mother has no education, the proportion of children with a hemoglobin level below 8.0 g/dl is higher (12 percent) in comparison with those whose mothers have a primary level (7 percent) or at least a secondary level (5 percent) of education.
- When the child lives in a household classified in the lowest wealth quintile, the proportion of children with a hemoglobin level below 8.0 g/dl is nearly four times higher (17 percent) than among those who live in households in the highest wealth quintile (more than 4 percent).

8.5 MALARIA PARASITEMIA

During the Continuous DHS of 2012-2013, the following two tests for malaria were used:

- A rapid diagnostic test (RDT), namely the SD BIOLINE Malaria Antigen P.f/Pan, which detects specific antigens for *Plasmodium falciparum* and other species without distinction. After obtaining informed consent, the interviewer collects a drop of blood on the strip of the RDT. The result of the test is available after 15 minutes and is immediately communicated to the parents or guardians of the child who has been recorded in the Household Questionnaire. Children testing positive on the RDT are either treated immediately with ACT according to the protocol of the Ministry of Health and Social Action if they show no contraindications or they are given a card referring them to a health facility.
- Microscopic examination of a thick blood drop smear.

The following section presents the results of the survey on the prevalence of malaria as estimated from thick drops of blood collected in the field and examined microscopically at the Laboratory of Parasitology of the Faculty of Medicine, Université Cheikh Anta Diop, in Dakar.

8.5.1 Principles and Methodology

Malaria parasitemia testing involved only children age 6-59 months and was performed on slides with thick blood drop smears. A sample of a drop of blood from the fingertip is placed on a microscope slide, which, after staining, is analyzed for precise identification of the *Plasmodium* parasite. An examination of a thick drop of blood has the advantage of being 20 times more sensitive than a thin smear. In the laboratory, each thick film is analyzed independently by two different operators, and a confirmation is made by a third operator in cases of a discrepancy between the first two.

Participation in the parasitemia test was subject to voluntary and informed consent of those responsible for the child. The interviewer recorded the response of parents/caregivers/other adults on the questionnaire and signed the questionnaire stating that he/she had read the consent and that the decision recorded on the questionnaire was that of the respondent.

Once consent was obtained, drops of blood were collected by pricking the fingertip. First, the finger was cleaned using gauze soaked in alcohol and allowed to dry in the open air. In a second step, the finger was pricked with a sterile, non-reusable retractable lancet. The first drop of blood was removed with a sterile dressing. The following drops were used for the thick smear. Two slides were prepared for each child tested.

The slides thus prepared were packed and sent to the central office of the survey for recording before being sent to the laboratory of the Department of Parasitology.

The tests were anonymous; no name or any identifying element was included on the blood samples. However, preprinted bar codes corresponding to numbers generated at random were glued to the slides used for the thick blood smear as well as for the questionnaires.

The risks associated with the procedure for collecting blood are considered low. The blood collection area was thoroughly cleansed with gauze pre-soaked in alcohol before the finger prick. The prick was performed with a sterile, non-reusable, retractable lancet that held a very small blade activated by a trigger. The flow of blood was stopped by pressure with gauze on the site of the prick. Once the bleeding stopped, the area was protected from infection by a band aid. In addition, samples were taken by accredited laboratory technicians who had received special upgraded training on the procedure and on the universal precautions to be observed in order to avoid transmitting pathogenic agents through blood. Lancets and all other instruments contaminated with blood were discarded at the end of the day in a bag for hazardous organic waste products, according to an established protocol.

The Laboratory of the Department of Parasitology was responsible for creating a data file containing the identification number of the sample and the results of all tests performed on each sample. Once verified, the data were sent to the main office of the survey.

8.5.2 Prevalence of Malaria Parasitemia in Children

The results in Table 8.10 indicate a very high testing coverage rate for malaria because a blood sample was taken for 96 percent of eligible children. This coverage is very high for all categories of children. Nevertheless, it is slightly lower for the youngest children (91 percent for those age 6-9 months); indeed, mothers refuse the test more frequently for very young children and blood samples are more difficult to obtain in these children than in older ones. Among the major regions, the coverage rate in the South (93 percent) is slightly lower than in other areas.

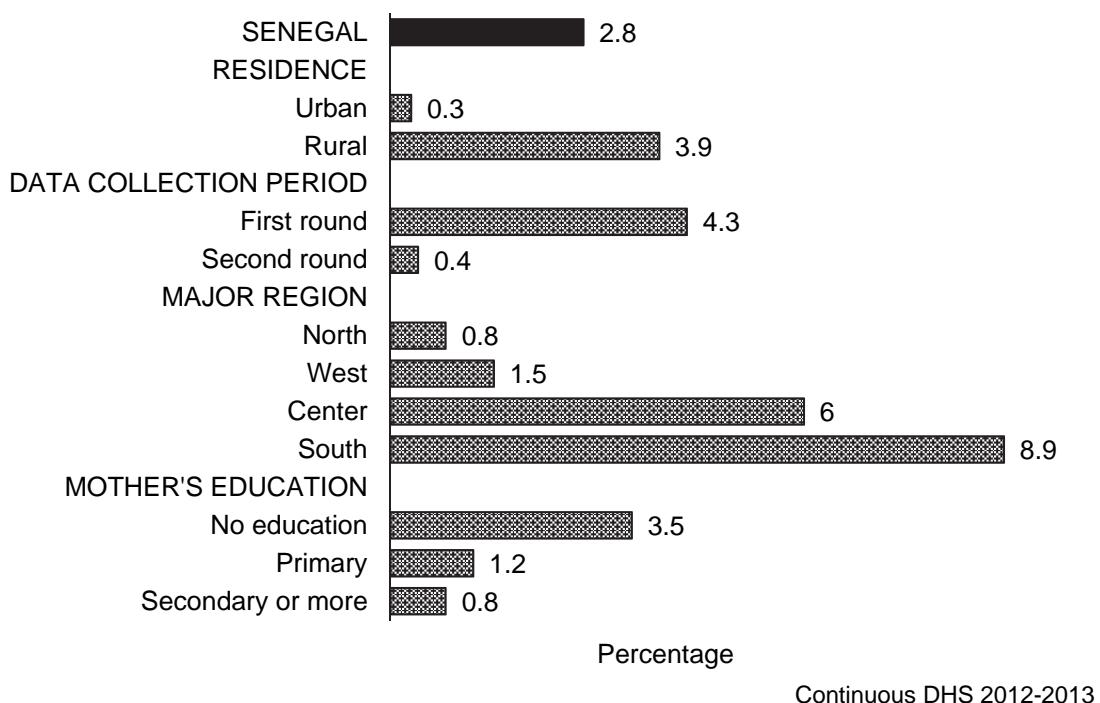

Parasite prevalence in children age 6-59 months was measured by the presence of the *Plasmodium* parasite in thick smears of blood from samples collected in the field and examined by microscope in the laboratory. The results of this testing are presented in Figure 8.1 and Table 8.11.

Figure 8.1 Prevalence of malaria parasitemia among children 6-59 months by background characteristics

The prevalence of malaria at the national level is estimated to be 2.8 percent according to the survey, which took place from September 2012 to June 2013, with a one-month break in February 2013. This rate was almost the same as in the EDS-MICS 2010-2011 (2.9 percent). The percentage of children infected with *Plasmodium* is lower among children age 10-11 months (1.1 percent) than children in other age groups where the prevalence varies between 2.3 percent and 3.1 percent. The survey did not reveal any significant difference by gender (2.6 percent for boys versus 3.0 percent in girls). In contrast, changes according to place of residence are significant: children in rural areas (4.0 percent) are much more affected by the disease than those in urban areas (0.4 percent). Depending on the time of collection, the variations are also significant (4.5 percent in the first round compared with 1.0 percent during the second round), reflecting the seasonality of malaria transmission in children age 6-59 months.

Differences between regions are also very significant. The major region of the South (9.3 percent), where the highest prevalence is observed, is followed distantly by the great Center region (2.2 percent). In contrast, the North (0.7 percent) and West (0.6 percent) have extremely low prevalences. According to the epidemiological profile for malaria, the prevalence in Zone I (corresponding to the two major regions of the North and West) is the lowest (0.7 percent) followed by Zone II (2.2 percent), which usually corresponds to the Center region. Zone III, which corresponds to the large South region, has the highest prevalence (9.3 percent) as might be expected. Finally, according to the index of wealth, the results show that the prevalence of malaria decreases from a maximum of 7.6 percent among children from households in the lowest wealth quintile to 0.4 percent among those from households in the highest quintile.

FEMALE CIRCUMCISION

Fatou Bintou NIANG

Key Findings

- The practice of female circumcision affects 18 percent of girls under age 15; 15 percent are circumcised before they reach age 10.
- Circumcision is most commonly practiced among daughters of Muslim women; girls living in the South and the North; and members of the Pular, Mandingue, Diola, and Soninké ethnic groups.
- The majority of girls are circumcised before age 5; among those now age 10-14, 83 percent were circumcised before age 5 compared with 13 percent at age 5-9, and 2 percent at age 10-14.
- For 7 percent of circumcised girls, the genital area was sewn closed. This form of circumcision is most often practiced by the Pular and Soninké ethnic groups.

The Continuous Demographic and Health Survey (Continuous DHS) collected information on the circumcision of girls under age 15. This chapter relates to the prevalence of circumcision, also called female genital mutilation (FGM); the age at which circumcision was performed; and the prevalence of infibulation, or closure of the genital area, among circumcised girls. Circumcision in general and infibulation in particular can seriously affect the health of girls by causing malfunction of the reproductive process, and the procedure may harm not only their physical but also their mental well-being.

Female circumcision is a cultural practice that finds its justification in the initiation rites for young girls practiced during the transition from childhood to adolescence and to adulthood in some communities. It covers the following four types of mutilation (WHO, 2008):

Type I: partial or total removal of the clitoris and/or the prepuce (clitoridectomy)

Type II: partial or total removal of the clitoris and the labia minora, with or without mutilation of the labia majora

Type III: narrowing of the vaginal orifice through creation of a covering seal by cutting and sewing together the labia minora and/or labia majora, with or without mutilation of the clitoris (infibulation)

Type IV: all other harmful procedures to the female genitalia for nontherapeutic purposes, such as pricking, piercing, incising, scarring, and cauterization

In Senegal, numerous measures have been taken to strengthen the campaigns organized to support the total abandonment of FGM. A law prohibiting FGM was enacted in 1999. A new action plan was adopted in 2010 to accelerate the abandonment of FGM by 2015. Drawing lessons from the evaluation of the implementation of the first action plan for 2000-2005 and taking into account the data collected for the first time as part of the DHS IV, the actions of the government and its partners reoriented around the following

guiding principles: a holistic and multisectoral approach based on human rights, community empowerment, and cross-border activities; advocacy at the national and international level; efficient systems for monitoring and evaluation; and improvement in coordination.

A study on the status of implementation of the law published in 2011 showed that its implementation remained limited; the law established the fear of criminal sanctions and, therefore, the practice moved underground, in some cases, to be practiced by doctors. Assessing the extent of the practice in the country is greatly needed and will measure the length of the road yet to be traveled to achieve total abandonment of this social practice.

The Continuous DHS 2012-2013 has been used to assess the prevalence of circumcision among girls under age 15. Therefore, all women who had one or more daughters under age 15 were asked whether one or more of them had been circumcised. In cases where one or more girls were circumcised, they were asked if the genital area had been sewn closed.

9.1 PREVALENCE OF CIRCUMCISION IN GIRLS UNDER AGE 15

Table 9.1 shows the percentage of all daughters under age 15 of all women interviewed who stated that their daughters were currently circumcised. Overall, 18 percent of young women under age 15 have been circumcised. However, the percentage of circumcised girls varies significantly by age of the girls. Thus, 11 percent of the girls who are currently under age 4 are circumcised, while almost double the percentage of girls age 5-9 are circumcised (21 percent) and one-quarter of girls who are currently age 10-14 are circumcised. This increase occurs in part because some girls are circumcised at an age older than 5. However, a very limited proportion of girls are circumcised after age 5; therefore, these differences according to the current age of the girls cannot only result from a greater exposure to the risk of being circumcised. They can also result from a decrease in the practice of circumcision among daughters in the youngest generation, those who today are age 5-9 and age 0-4.

According to the EDS-MICS of 2010-2011, 12 percent of girls age 0-9 were circumcised compared with 15 percent reported in the Continuous DHS of 2012-2013, which would seem to indicate an increase in the practice of circumcision over the past two years. However, the sequences of questions asked in 2010-2011 and in 2012-2013 differed significantly,¹ and, therefore, it is possible that during the Continuous DHS, women more readily reported the circumcision of their daughters than they did during the EDS-MICS. This apparent increase could, thus, simply reflect a bias in the statements of the women. One should, therefore, be careful in analyzing the results and interpreting any changes, which may not be real.

Circumcision of girls is much more prevalent among Muslims (18 percent of girls age 0-14) than among Christians (3 percent). Moreover, there are significant differences in prevalence based on ethnicity, region, and level of education of the mother. Indeed, the data indicate that the practice of FGM is mainly confined to the South (47 percent) and the North (33 percent). Ethnic groups where this practice is deeply

¹ Unlike the EDS-MICS of 2010-2011, during the Continuous DHS, women were not asked if they knew about circumcision, nor if they were themselves circumcised: they were asked directly about the circumcision of their daughters. Consequently, the prevalence of circumcision according to the Continuous DHS corresponds to the percentage of all circumcised daughters of all women age 15-49 (whether they know about circumcision or not). On the other hand, the prevalence of FGM presented in the report of the EDS-MICS (13 percent of girls age 0-9) corresponded to the percentage of all the circumcised daughters of women age 15-49 who knew about circumcision. Since these two levels of prevalence are not directly comparable, the prevalence of FGM was recalculated for the EDS-MICS by including in the calculation the daughters of women who did not know about circumcision and assuming that these daughters were not circumcised. This adjusted prevalence (comparable to that in the Continuous DHS) is 12 percent instead of 13 percent.

rooted in social norms, especially initiation rites, are concentrated in these areas. These ethnic areas of influence include the Mandingue (39 percent of girls age 0-14 are circumcised), Diola (35 percent) and Soninké (38 percent) in the South, and the Poulear (38%) in the North. In the regions of the Center and the West, the proportions of circumcised girls are low (2 percent and 5 percent, respectively, among those age 0-14), which is explained by the low prevalence observed among the Wolof and Sérer ethnic groups (less than 1 percent). In addition, the proportion of circumcised girls is much higher in rural areas (22 percent) than in urban areas (10 percent). It should also be emphasized that the proportion of girls who are circumcised decreases with an increasing level of education of the mother: 21 percent of girls whose mothers have no education are circumcised compared with 4 percent of girls whose mothers have attended up to secondary school.

An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

9.2 AGE AT CIRCUMCISION

Among the 1,252 girls age 0-14 who are circumcised, the vast majority (91 percent) were circumcised before age 5. Forty percent were circumcised before age 1 and 51 percent between ages 1 and 5 (Table 9.2). However, only girls currently age 10-14 have been exposed to the risk of being circumcised between birth and age 10, and the majority of them have also been exposed to the risk of being circumcised between age 10 and 15. Nevertheless, 83 percent of these girls were circumcised before age 5, and 13 percent were circumcised at age 5-9. Only 2 percent were circumcised at age 10-14.

Table 9.2 Daughter's age at circumcision

Percent distribution of circumcised daughters age 0-14, by age at circumcision according to current age, Continuous DHS, Senegal 2012-2013

Daughter's current age	Age at circumcision					Number of circumcised daughters	
	<1	1-4	5-9	10-14	Don't know/missing		
0-4	59.0	40.0	0.0	0.0	1.0	100	324
5-9	34.8	55.2	8.6	0.0	1.0	100	505
10-14	29.5	53.8	13.1	2.4	1.2	100	423
Total	39.5	51.0	8.0	0.6	1.1	100	1,252

9.3 INFIBULATION

At the time of the Continuous DHS, women who had reported that their daughters had been circumcised were asked if “the genital area had been closed,” which corresponds to an extreme form of FGM, called infibulation. The results presented in Table 9.3 relate to girls under age 10 whose circumcised genital area was closed. This extreme form of FGM affects 7 percent of girls age 0-9 (1 percent of all girls in this age group). According to the EDS-MICS of 2010-2011, 21 percent of circumcised girls age 0-9 underwent this form of circumcision. Because the two surveys are only separated by two years and most girls age 0-9 had already been included in the EDS-MICS (they were then age 0-7), it is not possible that the prevalence of infibulation would change so quickly in such a significant way. Again, taking into account the fact that the sequence of questions in 2010-2011 and in 2012-2013 differ significantly and that this apparent decrease could essentially be a bias in the statements of the women, one should therefore be very careful in analyzing the results and interpreting changes that may not be real.

Because of the low number of circumcised girls in certain sub-populations, it is difficult to analyze the differentials by background characteristics. It should, however, be noted that infibulation is practiced in particular by the Soninké (11 percent) and the Poulear (9 percent). In contrast, infibulation is seldom practiced among the Mandingue and the Diola, ethnic groups that nevertheless frequently practice circumcision.

De facto household population of women age 10-54 and interviewed women age 15-49; and percent distribution and percentage of eligible women who were interviewed (weighted), by five-year age groups, Continuous DHS, Senegal 2012-2013

Age group	Household population of women age 10-54	Interviewed women age 15-49		Percentage of eligible women interviewed
		Number	Percentage	
10-14	2,247	na	na	na
15-19	2,070	2,004	23.8	96.8
20-24	1,835	1,761	21.0	96.0
25-29	1,524	1,462	17.4	95.9
30-34	1,206	1,140	13.6	94.5
35-39	897	852	10.1	95.0
40-44	663	635	7.6	95.8
45-49	574	549	6.5	95.6
50-54	768	na	na	na
15-49	8,769	8,403	100.0	95.8

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview. Weights for both household population of women and interviewed women are household weights. Age is based on the Household Questionnaire.

na = Not applicable

Table C.3 Completeness of reporting

Percentage of observations missing information for selected demographic and health questions (weighted), Continuous DHS, Senegal 2012-2013

Subject	Reference group	Percentage with information missing	Number of cases
Birth date			
Month only	Births in the 15 years preceding the survey	2.37	15,819
Month and year	Births in the 15 years preceding the survey	0.02	15,819
Age at death	Deceased children born in the 15 years preceding the survey	0.00	1,276
Age/date at first union¹	Ever-married women age 15-49	0.98	5,975
Respondent's education	All women	4.09	6,078
Diarrhea in past 2 weeks	Living children age 0-59 months	2.88	6,298
Anthropometry²	Living children age 0-59 months (Household questionnaire)		
Height		2.88	6,298
Weight		2.80	6,298
Height or weight		2.88	6,298
Anemia³			
Anemia	Living children age 6-59 months (Household questionnaire)	2.88	6,298

¹ Both year and age missing.

² Child not measured.

³ Not tested.

Table C.4 Births by calendar years

Number of births, percentage with complete birth date, sex ratio at birth, and calendar year ratio by calendar year, according to living (L), dead (D), and total (T) children (weighted), Continuous DHS, Senegal 2012-2013

Calendar year	Number of births			Percentage with complete birth date ¹			Sex ratio at birth ²			Calendar year ratio ³

Note: Table is based on children who slept in the household the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the NCHS/CDC/WHO International Reference Population. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight.

¹ Includes children who are below –3 standard deviations (SD) from the International Reference Population median.

² Excludes children whose mothers were not interviewed.

³ First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval.

⁴ Includes children whose mothers are deceased.

⁵ For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

Table C.8 Need and demand for family planning among currently married women

Percentage of currently married women age 15-49 with unmet need for family planning, percentage with met need for family planning, the total demand for family planning, and the percentage of the demand for contraception that is satisfied, by background characteristics, Continuous DHS, Senegal 2012-2012

Background characteristic	Unmet need for family planning			Met need for family planning (currently using)			Total demand for family planning ¹			Percentage of demand satisfied ²	Percentage of demand satisfied by modern methods ³	Number of women

Note: Numbers in this table correspond to the revised definition of unmet need described in Bradley et al., 2012.

¹ Total demand is the sum of unmet need and met need.

² Percentage of demand satisfied is met need divided by total demand.

³ Modern methods include female sterilization, male sterilization, pill, IUD, injectables, implants, male condom, female condom, and lactational amenorrhea method (LAM).

⁴ Women who have had sexual intercourse within 30 days preceding the survey.

Table C.9 Number of antenatal care visits and timing of first visit

Percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by number of antenatal care (ANC) visits for the most recent live birth, and by the timing of the first visit, and among women with ANC, median months pregnant at first visit, according to residence, Continuous DHS Senegal, 2012-2013

Number and timing of ANC visits	Residence		
	Urban	Rural	Total

PRÉSENTATION ET CONSENTEMENT APRÈS INFORMATION

Bonjour. Je m'appelle _____. Je travaille pour l'Agence Nationale de la Statistique et de la Démographie en collaboration avec le Ministère de la Santé et de l'Action Sociale. Nous effectuons une enquête nationale sur la santé au Sénégal. Les informations que nous collectons aideront votre gouvernement à améliorer les services de santé. Votre ménage a été sélectionné pour cette enquête. Nous voudrions vous poser quelques questions sur votre ménage. Les questions prennent habituellement entre 15 et 20 minutes. Toutes les informations que vous nous donnerez sont strictement confidentielles et elles ne seront transmises à personne d'autres que les membres de l'équipe d'enquête. Vous n'êtes pas obligé de participer à cette enquête, mais nous espérons que vous accepterez d'y participer car votre opinion est très importante. S'il arrivait que je pose une question à laquelle vous ne voulez pas répondre, dîtes-le moi et je passerai à la question suivante ; vous pouvez également interrompre l'interview à n'importe quel moment.

Si vous souhaitez plus d'informations sur l'enquête, vous pouvez contacter les personnes figurant sur cette carte.

DONNEZ LA CARTE AVEC LES INFORMATIONS POUR CONTACTER CES PERSONNES

Avez-vous des questions à me poser ?
Puis-je commencer l'interview maintenant ?

PRÉSENTATION ET CONSENTEMENT INFORMÉ

CONSENTEMENT INFORMÉ

Bonjour. Je m'appelle Je travaille pour l'Agence Nationale de la Statistique et de la Démographie en collaboration avec le Ministère de la Santé et l'Action Sociale. Nous effectuons une enquête nationale sur la santé au SENEGAL. Les informations que nous collectons aideront votre gouvernement à améliorer les services de santé. Votre ménage a été sélectionné pour cette enquête. Les questions prennent habituellement entre 30 et 60 minutes. Toutes les informations que vous nous donnerez sont strictement confidentielles et elles ne seront transmises à personne d'autre que les membres de l'équipe d'enquête. Vous n'êtes pas obligée de participer à cette enquête mais nous espérons que vous accepterez d'y participer car votre opinion est très importante. S'il arrivait que je pose une question à laquelle vous ne voulez pas répondre, dites-le moi et je passerai à la question suivante ; vous pouvez également interrompre l'interview à n'importe quel moment.

Si vous souhaitez plus d'informations sur l'enquête, vous pouvez contacter la personne dont le nom figure sur la carte qui a déjà été donnée à votre ménage.

Avez-vous des questions ? Puis-je commencer l'interview maintenant ?
