## **Chapter 1: Introduction**

This report presents a series of poverty maps of Rwanda, based on data from the integrated living standards survey of 2013-14 (EICV4) and the 2012 Population and Housing Census.

In what follows we explain what a poverty map is, why it is useful, and how it may be constructed. We then present the technical details of the estimations that underpin the poverty maps, and evaluate the robustness of the results. The poverty maps themselves are shown in full colour in the last section of the report.

## **Chapter 2: What and Why**

A poverty map is simply a map that shows the incidence of poverty in different areas of the country. It allows the viewer to appreciate, at a glance, the geographic dimensions of poverty.

Apart from their intrinsic interest, poverty maps may be used to help guide the allocation of resources across local agencies or governmental units, in an effort to better target efforts to reach the poor. Potentially this works best if information on the incidence of poverty can be generated for small areas, allowing one to pinpoint the areas of most need (Baker and Grosh 1994).

In Rwanda, the standard measure of poverty is based on expenditure per adult equivalent: when this falls below the poverty line, the household is considered to be poor. Considerable care and attention has been given to the construction of an appropriate measure of expenditure, and to the formulation and updating over time of the poverty line (NISR 2016).

The measurement of poverty requires detailed information, which can only be obtained with an extensive survey questionnaire. The cost of gathering these data limits the survey size: 14,419 households were surveyed in EICV4. While this allows one to measure poverty quite accurately at the national and provincial level, the samples are too small at the level of the sector or cell – the smallest institutional units in Rwanda – for one to be able to measure poverty directly at this degree of disaggregation. To work around this problem, so as to be able to produce detailed poverty maps, one needs to turn to the techniques of small-area estimation, which are described in the next section.

## **Chapter 3: Small-Area Estimation**

Given that we have data from a high-quality, but relatively small, survey of household living standards (EICV4), how might one estimate the poverty rates for every small area in Rwanda?

The key idea is to combine the detailed information from EICV4 with the one source of recent data that has information on every household, which is the Population and Housing Census of 2012 (henceforth the “Census”). While the Census covered every household, it only collected information on a limited number of variables, such as the conditions of the housing unit, and family demographic characteristics, and these are not enough for one to measure directly whether a family has low levels of expenditure and is therefore poor.

The method proceeds in five steps.

1. Identify variables for which information was collected in a compatible fashion both in the EICV4 survey and in the Census, and which are likely to be correlated with expenditure per adult equivalent (and hence with poverty).
2. Using these variables, construct a logistic regression model using the EICV4 data that predicts whether a household is poor or not in 2013/14. Check that this model is sensible, robust, and accurate in its predictions.
3. Use the regression model from step 2, along with the information from the Census, to predict the poverty rate of every household in the country.
4. Aggregate the information from step 3 to get the proportion of people in each of the 2,148 cells (or 416 sectors) who are estimated to be poor.
5. Create a map of the poverty rates for each cell (or sector), using a palette of colours that makes it easy to identify the areas that have higher or lower levels of poverty.

In the following sub-sections we discuss these steps in more detail.

### 3.1 Identifying Variables

We have identified twenty relevant questions that ask for the same information in the Census as in the EICV4. These are listed in Table 3.1, where we have sorted them into environmental, housing, social, demographic, economic, and geographic variables. Our earlier work shows that these variables are closely associated with the incidence of poverty (NISR 2016).

Four of these variables are continuous (such as the household size, or age of the head of household), three are binary (such as the gender of the head of household, or whether the household has a mobile phone), and the other thirteen are categorical variables with multiple categories (such as the type of fuel used for cooking, or the district in which the household is located).

### 3.2 The Logistic Regression Model

Our goal in this step is to build a regression model that predicts whether a household is poor or not, using data from the living standards survey of 2013-14 (EICV4). For every household in this survey we have a direct measure of whether they are poor or not; this variable, which we denote by  $y_i$ , takes on a value of 1 (if the household  $i$  is poor) or 0 (if they are not poor).

**Technical note.** We measure poverty using the headcount index, which estimates the proportion of households in an area  $a$  that are poor ( $p_a$ ). This is equivalent to saying that the probability that a randomly chosen household from the area is poor is  $p_a$ .

The variable  $y_i$  has a Bernoulli distribution with probabilities  $p_i$ . The odds that the  $i^{th}$  household is poor are given by  $o(y_i) = p_i/(1 - p_i)$ , and the logit of the odds is given by the natural log of the odds, so  $\text{logit}(y_i) = \ln(o(y_i))$ . It is convenient to model the logit as a linear function of the  $k$  predictor variables, which leads to the following:

$$\text{logit}(y_i) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_k x_k. \quad (1)$$

Here, the  $x_i$  are the variables that we have identified in step 1, and the  $\beta_i$  are parameters that need to be estimated, which we do using a maximum likelihood method that also takes into account the sample design of EICV4 (Hosmer, Lemenshow, and Sturdivant 2013).

Using Eqn. (1), we can use the values of the  $x_i$  for any household, along with the estimated values of the  $\beta_i$ , to find the logit, and from there the odds, and thence the estimated probability that the household is poor, given by  $\hat{p}_i$ .

An important characteristic of the Bernoulli distribution is that the expected value of the random variable  $y_i$  is the same as the probability that the household is poor (i.e. of  $p_i$ ). It follows that the estimate of the number of poor households in any community such as a cell or sector is given by  $\sum_i \hat{p}_i$ , so an estimate of the poverty rate in a community of  $n$  members is given by  $\sum_i \hat{p}_i/n$ .

The results of estimating the logistic regression, using the EICV4 data, are shown in Table 3.1. The first column of numbers shows the mean values of each variable (for continuous variables), or the frequency with which each category occurs (for categorical variables).

The next column in Table 3.1 gives the coefficients of the logistic regression. Within each categorical variable, one category serves as the reference point, and the coefficients show how the logit varies relative to the reference category, holding all other effects constant. The coefficients are of limited interest in their own right, given that we are focused on the ability of the estimated equation to predict poverty status overall, rather than on testing the significance of individual effects. The penultimate column shows the p-values for each coefficient: the lower the p-value, the higher the statistical significance of the estimated coefficient.

The final column in Table 3.1 measures the statistical significance of including the variable in the equation. In every case these p-values are very small, which is strong

evidence that they belong in the model, and are helpful in estimating whether a household is, or is not, poor.

### 3.3 Rolling out the Model

We now apply the estimated equation from section 3.2, which is based on the EICV4 data, to estimate the probability, using data from the Census for every household in the country, that it is poor (i.e.  $\hat{p}_i$ ).

But before using these results to build maps, we would like to get a better sense of whether our modelling exercise does a good job of predicting the poverty status of households in an area.

A good way to test our model is to compare the poverty rates that are actually observed with those predicted by the model. Rwanda has 30 districts, and the sample size of the EICV4 survey is large enough to allow us to estimate directly the headcount poverty rate for each district, as well as generate a 95% confidence interval around these estimates. These poverty rates and intervals are shown in the first three columns of numbers in Table 3.2.

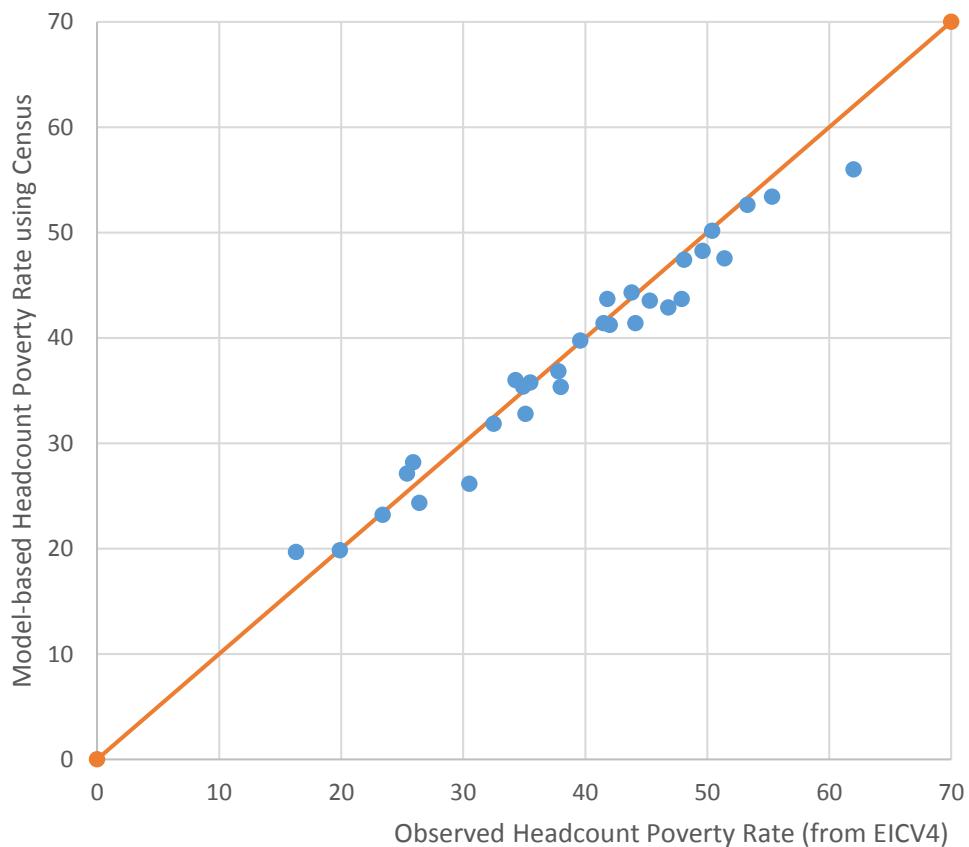

Next, for each district we find the estimate of poverty that is generated using our model as applied to the Census data; as noted above, this involves computing the mean value of the estimated probabilities (i.e. of the  $\hat{p}_i$ ) by district. These numbers are shown in the last column of Table 3.2. If our model is a good one, the poverty rates generated by the model applied to Census data, should be close to the poverty rates estimated directly from the EICV4 survey data.

The two sets of poverty estimates are indeed close. This may be seen from Table 3.2, where the model-based results all fall within the 95% confidence interval of the directly-estimated survey figures. This is also clear from Figure 3.1, which graphs the observed poverty rate for each district on the horizontal axis, and the model-based Census estimates on the vertical axis: the two measures closely hug the 45° line.

**Table 3. 2: Observed and Model-Predicted Poverty Headcount Index by District**

Province	District	Poverty Headcount Rate from EICV4			Model-based mean using Census data

**Figure 3. 1: Comparison of Observed (from EICV4) and Model-Based (using Census) Poverty Rates by District**

### 3.4 Aggregating the Information

We are now ready to estimate the poverty rate for each cell, and each sector, in the country. The method is as outlined in section 3.3: for each household, use the Census data, and the model estimated in section 3.2., to get a value of  $\hat{p}_i$  for every household. Then find the average of these estimates for every cell and sector. Annex 1 lists every sector by province, sorted from those with the lowest to those with the highest estimated poverty rates. Annex 2 does the same thing for cells.

One way to summarize the results is to show the number and percentage of cells in each province that are associated with different incidences of poverty. Table 3.3 shows that there is great variation in these percentages in Kigali City: 48% of cells had poverty rates below 20%, while 16% had rates above 50%; this is in contrast to the Eastern Province, where just 5% of cells had very low poverty rates, and only 7% had poverty rates above 50%. Similar patterns are found in Table 3.4, which repeats this exercise, but using the 416 sectors rather than the 2,147 cells.

**Table 3. 3: Distribution of Cells by Category of Poverty and by Province**

	%	7.2	10.8	26.7	36.1	18.8	0.5%	100.0

### 3.5 Mapping the Data

The final step is to map the data in a visually compelling way. In the maps that follow, national parks are shown in dark green, and lakes in blue. We distinguish six levels of poverty intensity, as follows:

**Table 3. 5: Mapping the data in a visually compelling way**

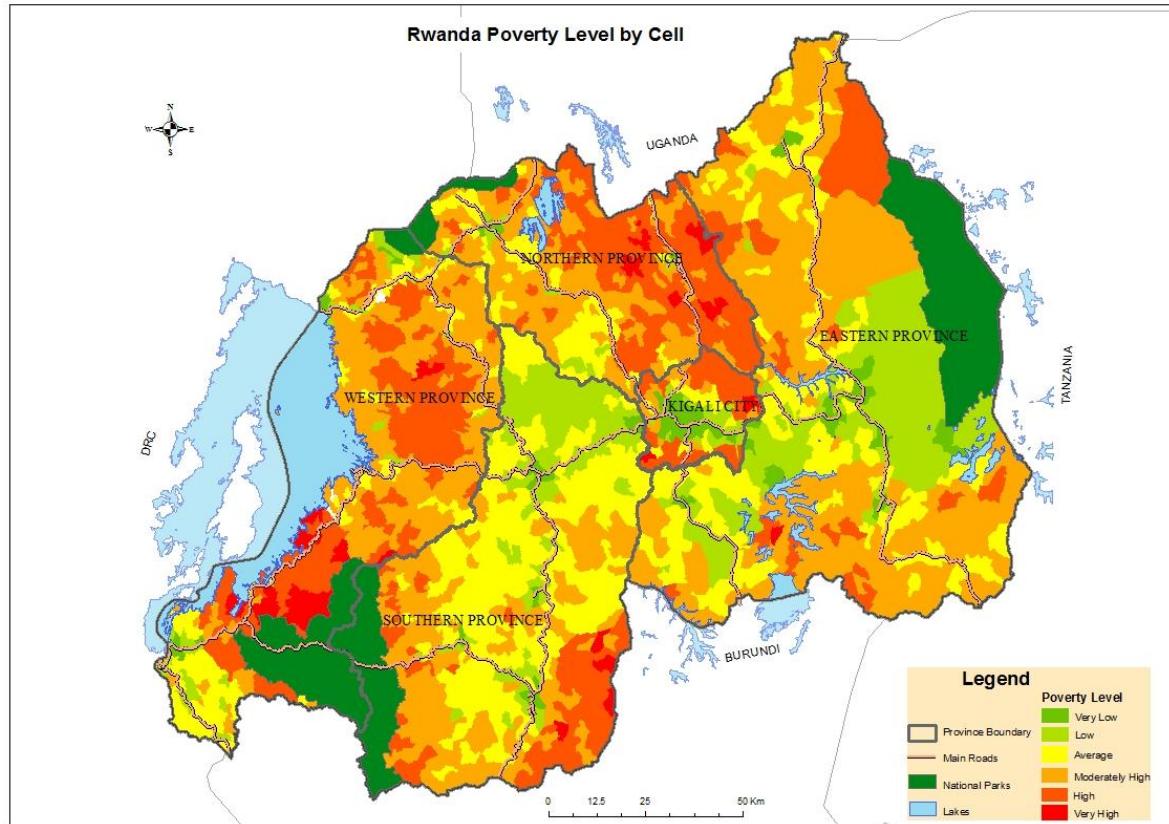

Poverty is:	Poverty rate	Map colour	% of cells	% of sectors
Very low	Under 20%	Green	6.6	7.2
Low	20 – 29.9%	Light green	11.6	10.8
"Average"	30 – 39.9%	Yellow	24.4	26.7
Moderately high	40 – 49.9%	Orange	36.0	36.1
High	50 – 59.9%	Light red	19.5	18.8
Very high	60% or higher	Dark red	1.9	0.5

As one moves from green through yellow to orange and dark red, the poverty rate in the area is higher. The average poverty rate in 2013/14 was 39.1%, based on the EICV4 data; just 7% of cells or sectors had poverty rates below 20%, while about one in five areas had poverty rates of at least 50%.

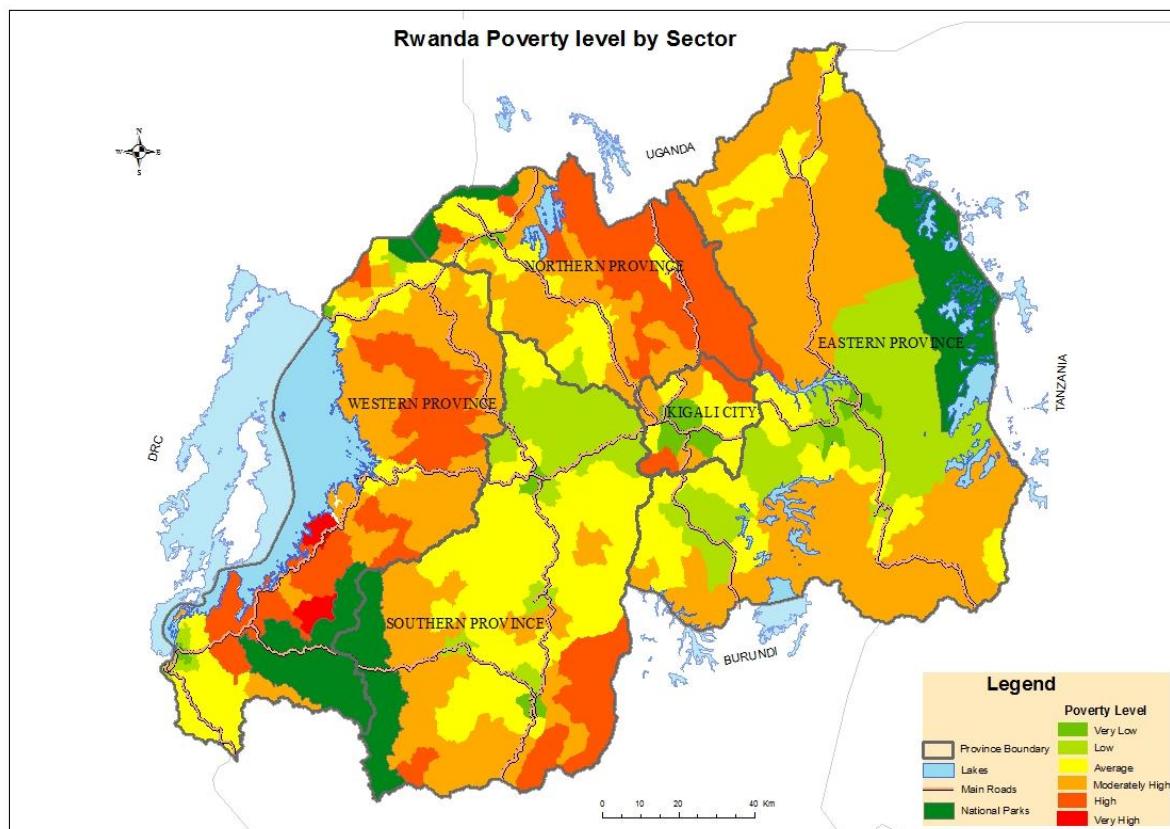

The maps shown in Maps 3.1 and 3.2 show the poverty rates across the whole country, first based on cells, and then based on sectors. The pattern is the same in each case, although it is more fine-grained in the first (cell-based) map: there is an axis of less-poor areas extending east and west of Kigali, with a great arc of high-poverty areas in the more distant north, west, and part of the south.

The subsequent maps provide detailed poverty maps for each of the five provinces, first at the level of each cell (Maps 3.3 through 3.7), and then at the sectoral level (Maps 3.8 through 3.12). One of the more obvious patterns to emerge from these maps is the comparatively low incidence of poverty in larger towns, and along the main roads.

### **Annex 3: Contributors to the Poverty Mapping Analysis Report**

#### **National Coordinator**

Yusuf MURANGWA, Director General-NISR

#### **Technical Coordinator**

Dominique HABIMANA, Director of Statistical Methods, Research and Publication – NISR

#### **Analysis Team**

- Yusuf MURANGWA, Director General – NISR
- Dominique HABIMANA, Director of Statistical Methods and Research- NISR
- Dr Mohammed F. ABULATA, Senior Technical Advisor – NISR
- Appel Derek NKURUNZIZA, Team Leader in charge of Statistical Methods – NISR
- Baba Ali MWANGO, Team Leader in charge of Economic Censuses – NISR
- Roger KAMANA, Sampling Statistician-NISR
- Serge MUGABO, Statistician Economist-NISR
- Beatrice UWAYEZU, Team Leader in charge of Population Censuses-NISR

#### **Analysis Review**

- Professor Jonathan HAUGHTON, International Poverty Expert – Suffolk University (USA)
- Professor Dominique HAUGHTON, International Poverty Expert – Bentley University (USA)

#### **Edit and Design**

Nyirimanzi Jean Claude, Team Leader in charge of Research, Publication and Dissemination - NISR
